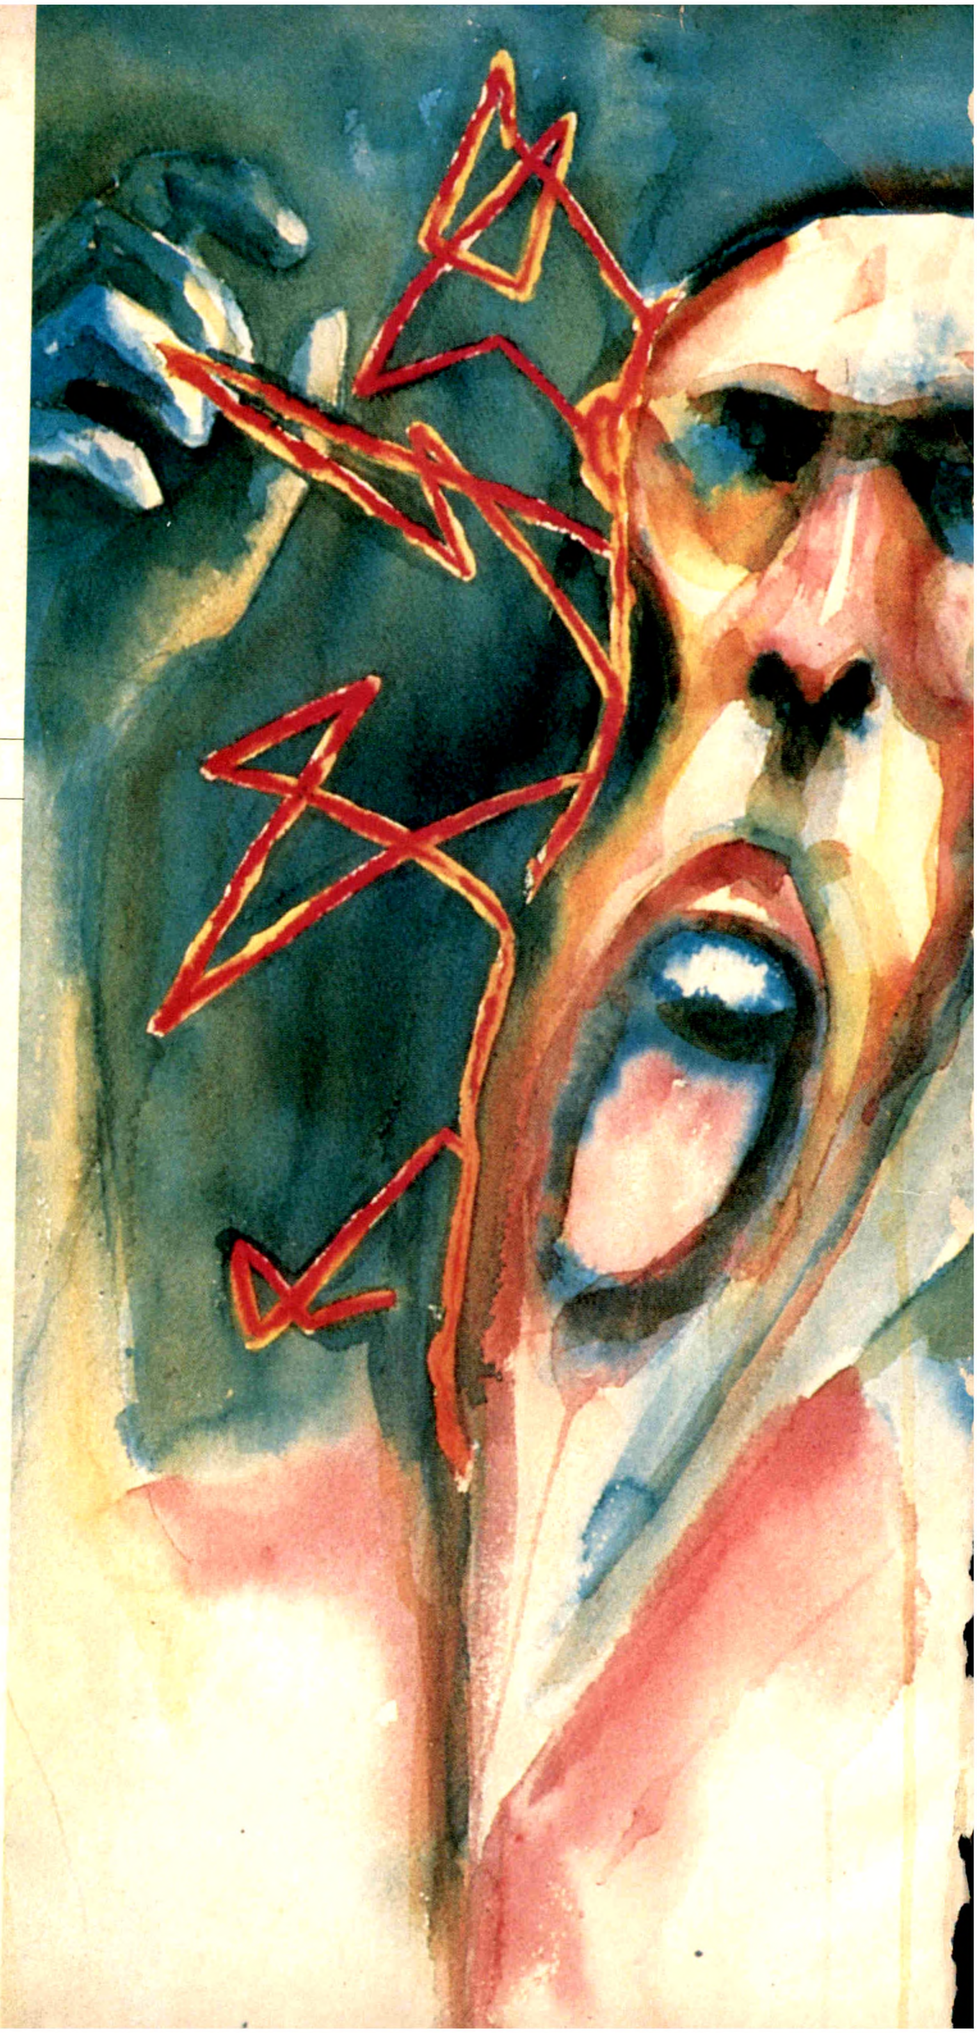
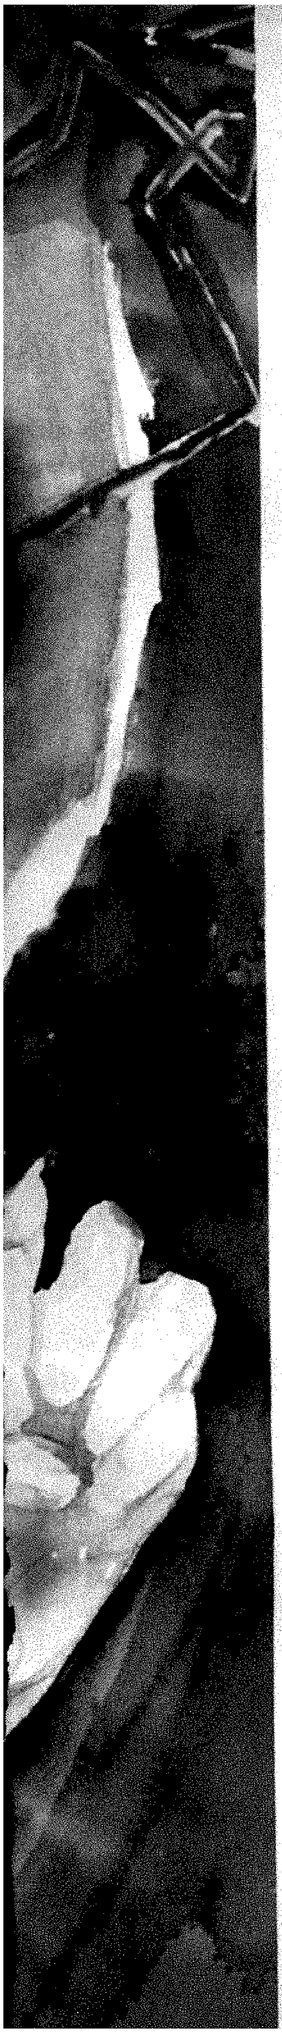
HEADACHE DESCRIBED



"Headache"—a personal interpretation of headache pain by John Crowley, a headache patient.



P24,923

HEADACHE RELIEVED

Effectively treats the pain of muscle contraction headache as well as the anxiety and tension that magnify it

FIORINAL WITH CODEINE III CAPSULES

(Each capsule contains: codeine phosphate 30 mg [Warning: May be habit-forming]; butalbital 50 mg [Warning: May be habit-forming]; caffeine 40 mg; and aspirin 325 mg)

Potent relief of tension headache pain

Please see brief summary on following page.

© 1990 Sandoz Pharmaceuticals Corporation

FWC-0790-01

SANDOZPHARMACEUTICALS
Corporation, E. Hanover, NJ 07936 (201) 503-7500

BRIEF SUMMARY: Please see package insert for full prescribing information.

FIORINAL® WITH CODEINE CIII CAPSULES

(Codeine phosphate USP, 30 mg [warning: may be habit forming]; butalbital USP, 50 mg [warning: may be habit forming]; caffeine USP, 40 mg; aspirin USP, 325 mg)

CAUTION: Federal law prohibits dispensing without prescription.

CONTRAINDICATIONS: Fiorinal® with Codeine is contraindicated under the following conditions:

1. Hypersensitivity or intolerance to aspirin, caffeine, butalbital or codeine.
2. Patients with a hemorrhagic diathesis (e.g., hemophilia, hypoprothrombinemia, von Willebrand's disease, the thrombocytopenias, thrombasthenia and other ill-defined hereditary platelet dysfunctions, severe vitamin K deficiency and severe liver damage.)
3. Patients with the syndrome of nasal polyps, angioedema and bronchospastic reactivity to aspirin or other nonsteroidal anti-inflammatory drugs. Anaphylactoid reactions have occurred in such patients.
4. Peptic ulcer or other serious gastrointestinal lesions.
5. Patients with porphyria.

WARNINGS: Therapeutic doses of aspirin can cause anaphylactic shock and other severe allergic reactions. It should be ascertained if the patient is allergic to aspirin, although a specific history of allergy may be lacking.

Significant bleeding can result from aspirin therapy in patients with peptic ulcer or other gastrointestinal lesions, and in patients with bleeding disorders.

Aspirin administered pre-operatively may prolong the bleeding time.

In the presence of head injury or other intracranial lesions, the respiratory depressant effects of codeine and other narcotics may be markedly enhanced, as well as their capacity for elevating cerebrospinal fluid pressure. Narcotics also produce other CNS depressant effects, such as drowsiness, that may further obscure the clinical course of patients with head injuries.

Codeine or other narcotics may obscure signs on which to judge the diagnosis or clinical course of patients with acute abdominal conditions.

Butalbital and codeine are both habit-forming and potentially abusable. Consequently, the extended use of Fiorinal® with Codeine is not recommended.

Results from epidemiologic studies indicate an association between aspirin and Reye Syndrome. Caution should be used in administering this product to children, including teenagers, with chicken pox or flu.

PRECAUTIONS: General: Fiorinal® with Codeine should be prescribed with caution for certain special-risk patients such as the elderly or debilitated, and those with severe impairment of renal or hepatic function, coagulation disorders, or head injuries.

Aspirin should be used with caution in patients on anticoagulant therapy and in patients with underlying hemostatic defects.

Precautions should be taken when administering salicylates to persons with known allergies. Hypersensitivity to aspirin is particularly likely in patients with nasal polyps, and relatively common in those with asthma.

Information for Patients: Patients should be informed that Fiorinal® with Codeine contains aspirin and should not be taken by patients with an aspirin allergy.

Fiorinal® with Codeine may impair the mental and/or physical abilities required for performance of potentially hazardous tasks such as driving a car or operating machinery. Such tasks should be avoided while taking Fiorinal® with Codeine.

Alcohol and other CNS depressants may produce an additive CNS depression when taken with Fiorinal® with Codeine, and should be avoided.

Codeine and butalbital may be habit-forming. Patients should take the drug only for as long as it is prescribed, in the amounts prescribed, and no more frequently than prescribed.

Laboratory Tests: In patients with severe hepatic or renal disease, effects of therapy should be monitored with serial liver and/or renal function tests.

Drug Interactions: The CNS effects of butalbital may be enhanced by monoamine oxidase (MAO) inhibitors.

In patients receiving concomitant corticosteroids and chronic use of aspirin, withdrawal of corticosteroids may result in salicylism because corticosteroids enhance renal clearance of salicylates and their withdrawal is followed by return to normal rates of renal clearance.

Fiorinal® with Codeine may enhance the effects of:

1. Oral anticoagulants, causing bleeding by inhibiting prothrombin formation in the liver and displacing anticoagulants from plasma protein binding sites.
2. Oral antidiabetic agents and insulin, causing hypoglycemia by contributing an additive effect, if dosage of Fiorinal® with Codeine exceeds maximum recommended daily dosage.
3. 6-mercaptopurine and methotrexate, causing bone marrow toxicity and blood dyscrasias by displacing these drugs from secondary binding sites, and, in the case of methotrexate, also reducing its excretion.
4. Non-steroidal anti-inflammatory agents, increasing the risk of peptic ulceration and bleeding by contributing additive effects.
5. Other narcotic analgesics, alcohol, general anesthetics, tranquilizers such as chlordiazepoxide, sedative-hypnotics, or other CNS depressants, causing increased CNS depression.

Fiorinal® with Codeine may diminish the effects of: Uricosuric agents such as probenecid and sulfinpyrazone, reducing their effectiveness in the treatment of gout. Aspirin competes with these agents for protein binding sites.

Drug/Laboratory Test Interactions

Aspirin: Aspirin may interfere with the following laboratory determinations in blood: serum amylase, fasting blood glucose, cholesterol, protein, serum glutamic-oxalacetic transaminase (SGOT), uric acid, prothrombin time and bleeding time. Aspirin may interfere with the following laboratory determinations in urine: glucose, 5-hydroxyindoleacetic acid, Gerhardt ketone, vanillylmandelic acid (VMA), uric acid, diacetic acid, and spectrophotometric detection of barbiturates.

Codeine: Codeine may increase serum amylase levels.

Carcinogenesis, Mutagenesis, Impairment of Fertility: Adequate long-term studies have been conducted in mice and rats with aspirin, alone or in combination with other drugs, in which no evidence of carcinogenesis was seen. No adequate studies have been conducted in animals to determine whether aspirin has a potential for mutagenesis or impairment of fertility. No adequate studies have been conducted in animals to determine whether butalbital has a potential for carcinogenesis, mutagenesis, or impairment of fertility.

Usage in Pregnancy

Teratogenic Effects: Pregnancy Category C — Animal reproduction studies have not been conducted with Fiorinal® with Codeine. It is also not known whether Fiorinal® with Codeine can cause fetal harm when administered to a pregnant woman or can affect reproduction capacity. Fiorinal® with Codeine should be given to a pregnant woman only when clearly needed.

Nonteratogenic Effects: Although Fiorinal® with Codeine was not implicated in the birth defect, a female infant was born with lissencephaly, pachygyria and heterotopic gray matter. The infant was born 8 weeks prematurely to a woman who had taken an average of 90 Fiorinal® with Codeine capsules each month from the first few days of pregnancy. The child's development was mildly delayed and from one year of age she had partial simple motor seizures.

Withdrawal seizures were reported in a two-day-old male infant whose mother had taken a butalbital-containing drug during the last 2 months of pregnancy. Butalbital was found in the infant's serum. The infant was given phenobarbital 5mg/kg, which was tapered without further seizure or other withdrawal symptoms.

Studies of aspirin use in pregnant women have not shown that aspirin increases the risk of abnormalities when administered during the first trimester of pregnancy. In controlled studies involving 41,337 pregnant women and their offspring, there was no evidence that aspirin taken during pregnancy caused stillbirth, neonatal death or reduced birth weight. In controlled studies of 50,282 pregnant women and their offspring, aspirin administration in moderate and heavy doses during the first four lunar months of pregnancy showed no teratogenic effect.

Reproduction studies have been performed in rabbits and rats at doses up to 150 times the human dose and have revealed no evidence of impaired fertility or harm to the fetus due to codeine.

Therapeutic doses of aspirin in pregnant women close to term may cause bleeding in mother, fetus, or neonate. During the last 6 months of pregnancy, regular use of aspirin in high doses may prolong pregnancy and delivery.

Labor and Delivery: Ingestion of aspirin prior to delivery may prolong delivery or lead to bleeding in the mother or neonate. Use of codeine during labor may lead to respiratory depression in the neonate.

Nursing Mothers: Aspirin, caffeine, barbiturates and codeine are excreted in breast milk in small amounts, but the significance of their effects on nursing infants is not known. Because of potential for serious adverse reactions in nursing infants from Fiorinal® with Codeine, a decision should be made whether to discontinue nursing or to discontinue the drug, taking into account the importance of the drug to the mother.

Pediatric Use: Safety and effectiveness in children below the age of 12 have not been established.

ADVERSE REACTIONS: Commonly Observed: The most commonly reported adverse events associated with the use of Fiorinal® with Codeine and not reported at an equivalent incidence by placebo-treated patients were nausea and/or abdominal pain, drowsiness, and dizziness.

Associated with Treatment Discontinuation: Of the 382 patients treated with Fiorinal® with Codeine in controlled clinical trials, three (0.8%) discontinued treatment with Fiorinal® with Codeine because of adverse events. One patient each discontinued treatment for the following reasons: gastrointestinal upset, lightheadedness and heavy eyelids, and drowsiness and generalized tingling.

Incidence in Controlled Clinical Trials: The following table summarizes the incidence rates of the adverse ev reported by at least 1% of the Fiorinal® with Codeine treated patients in controlled clinical trials comparing Fiori with Codeine to placebo, and provides a comparison to the incidence rates reported by the placebo-treated patie

The prescriber should be aware that these figures cannot be used to predict the incidence of side effec the course of usual medical practice where patient characteristics and other factors differ from those that preva in the clinical trials. Similarly, the cited frequencies cannot be compared with figures obtained from other clin investigations involving different treatments, uses, and investigators.

Adverse Events Reported by at Least 1% of Fiorinal® with Codeine Treated Patients During Placebo Controlled Clinical Trials

Body System/ Adverse Event	Incidence Rate of Adverse Events Fiorinal®/Codeine (N = 382)	Placebo (N = 37
Central Nervous		
Drowsiness	2.4%	0.5%
Dizziness/Lightheadedness	2.6%	0.5%
Intoxicated Feeling	1.0%	0%
Gastrointestinal		
Nausea/Abdominal Pain	3.7%	0.8%

Other Adverse Events Reported During Controlled Clinical Trials: The listing that follows represents the proporti of the 382 patients exposed to Fiorinal® with Codeine while participating in the controlled clinical trials who reporte on at least one occasion, an adverse event of the type cited. All reported adverse events, except those alrea presented in the previous table, are included. It is important to emphasize that, although the adverse events report did occur while the patient was receiving Fiorinal® with Codeine, the adverse events were not necessarily caus by Fiorinal® with Codeine.

Adverse events are classified by body system and frequency. "Frequent" is defined as an adverse event wh occurred in at least 1/100 (1%) of the patients; all adverse events listed in the previous table are frequent. "Infrequ is defined as an adverse event that occurred in less than 1/100 patients but at least 1/1000 patients. All adve events tabulated below are classified as infrequent.

Central Nervous: headache, shaky feeling, tingling, agitation, fainting, fatigue, heavy eyelids, high energy, hot spe numbness, and sluggishness.

Autonomic Nervous: dry mouth and hyperhidrosis.

Gastrointestinal: vomiting, difficulty swallowing, and heartburn.

Cardiovascular: tachycardia.

Musculoskeletal: leg pain and muscle fatigue.

Genitourinary: diuresis.

Miscellaneous: pruritus, fever, earache, nasal congestion, and tinnitus.

Voluntary reports of adverse drug events, temporally associated with Fiorinal® with Codeine, that have been rece since market introduction and that were not reported in clinical trials by the patients treated with Fiorinal® Codeine, are listed below. Many or most of these events may have no causal relationship with the drug and listed according to body system.

Central Nervous: Abuse, addiction, anxiety, depression, disorientation, hallucination, hyperactivity, insomnia, li decrease, nervousness, neuropathy, psychosis, sedation, sexual activity increase, slurred speech, twitching, unc sciousness, vertigo.

Autonomic Nervous: epistaxis, flushing, miosis, salivation.

Gastrointestinal: anorexia, appetite increased, constipation, diarrhea, esophagitis, gastroenteritis, gastrointesti spasm, hiccup, mouth burning, pyloric ulcer.

Cardiovascular: chest pain, hypotensive reaction, palpitations, syncope.

Skin: erythema, erythema multiforme, exfoliative dermatitis, hives, rash, toxic epidermal necrolysis.

Urinary: kidney impairment, urinary difficulty.

Miscellaneous: allergic reaction, anaphylactic shock, cholangiocarcinoma, drug interaction with erythromy (stomach upset), edema.

The following adverse drug events may be borne in mind as potential effects of the components of Fiorin with Codeine. Potential effects of high dosage are listed in the *OVERDOSAGE* section of this insert.

Aspirin: occult blood loss, hemolytic anemia, iron deficiency anemia, gastric distress, heartburn, nausea, pe ulcer, prolonged bleeding time, acute airway obstruction, renal toxicity when taken in high doses for prolon periods, impaired urate excretion, hepatitis.

Caffeine: cardiac stimulation, irritability, tremor, dependence, nephrotoxicity, hyperglycemia

Codeine: nausea, vomiting, drowsiness, lightheadedness, constipation, pruritus.

DRUG ABUSE AND DEPENDENCE: Fiorinal® with Codeine is controlled by the Drug Enforcement Administra and is classified under Schedule III.

Codeine: Codeine can produce drug dependence of the morphine type and, therefore, has the potentia being abused. Psychological dependence, physical dependence, and tolerance may develop upon repe administration and it should be prescribed and administered with the same degree of caution appropriate to use of other oral narcotic medications.

Butalbital: *Barbiturates may be habit forming:* Tolerance, psychological dependence, and physical depend may occur especially following prolonged use of high doses of barbiturates. The average daily dose for the barb addict is usually about 1,500 mg. As tolerance to barbiturates develops, the amount needed to maintain the s level of intoxication increases; tolerance to a fatal dosage, however, does not increase more than two-fold. As occurs, the margin between an intoxication dosage and fatal dosage becomes smaller. The lethal dose of a barbitu is far less if alcohol is also ingested. Major withdrawal symptoms (convulsions and delirium) may occur within hours and last up to 5 days after abrupt cessation of these drugs. Intensity of withdrawal symptoms gradually dec over a period of approximately 15 days. Treatment of barbiturate dependence consists of cautious and gr withdrawal of the drug. Barbiturate-dependent patients can be withdrawn by using a number of different withd regimens. One method involves initiating treatment at the patient's regular dosage level and gradually decrea the daily dosage as tolerated by the patient.

OVERDOSAGE: The toxic effects of acute overdosage of Fiorinal® with Codeine capsules are attributable m to the barbiturate and codeine components, and, to a lesser extent, aspirin. Because toxic effects of caffeine in very high dosages only, the possibility of significant caffeine toxicity from Fiorinal® with Codeine overd is unlikely.

Signs and Symptoms: Symptoms attributable to *acute barbiturate poisoning* include drowsiness, confusion coma; respiratory depression; hypotension; shock. Symptoms attributable to *acute aspirin poisoning* include hyper acid-base disturbances with development of metabolic acidosis; vomiting and abdominal pain; tinnitus; hyperthe hypoprothrombinemia; restlessness; delirium; convulsions. *Acute caffeine poisoning* may cause insomnia, restless tremor, and delirium, tachycardia and extrasystoles. Symptoms of *acute codeine poisoning* include the triad of: pin pupils, marked depression of respiration, and loss of consciousness. Convulsions may occur.

Treatment: The following paragraphs describe one approach to the treatment of overdose with Fiorinal® Codeine. However, because strategies for the management of an overdose continually evolve, consultation regional poison control center is strongly encouraged.

Treatment consists primarily of management of barbiturate intoxication, reversal of the effects of codeine the correction of the acid-base imbalance due to salicylism. Vomiting should be induced mechanically or with e in the conscious patient. Gastric lavage may be used if the pharyngeal and laryngeal reflexes are prese if less than 4 hours have elapsed since ingestion. A cuffed endotracheal tube should be inserted before lavage of the unconscious patient and when necessary to provide assisted respiration. Diuresis, alkaliza the urine, and correction of electrolyte disturbances should be accomplished through administration of intrav fluids such as 1% sodium bicarbonate and 5% dextrose in water.

Meticulous attention should be given to maintaining adequate pulmonary ventilation. Correction of hypote may require the administration of levarterenol bitartrate or phenylephrine hydrochloride by intravenous infus severe cases of intoxication, peritoneal dialysis, hemodialysis, or exchange transfusion may be lifes Hypoprothrombinemia should be treated with vitamin K, intravenously.

Methemoglobinemia over 30% should be treated with methylene blue by slow intravenous administration.

Naloxone, a narcotic antagonist, can reverse respiratory depression and coma associated with opioid ove Typically, a dose of 0.4 mg to 2 mg is given parenterally and may be repeated if an adequate response achieved. Since the duration of action of codeine may exceed that of the antagonist, the patient should b under continued surveillance and repeated doses of the antagonist should be administered as needed to m adequate respiration. A narcotic antagonist should not be administered in the absence of clinically significant resp or cardiovascular depression.

Toxic and Lethal Doses:

Butalbital: toxic dose 1.0 g (adult); lethal dose 2.0-5.0 g
Aspirin: toxic blood level greater than 30 mg/100 mL; lethal dose 10-30 g (adult)
Caffeine: toxic dose greater than 1.0 g; lethal dose unknown
Codeine: lethal dose 0.5-1.0 g (adult)

American Society of Neuroimaging
14th Annual Meeting
February 5-10, 1991
Hilton at Walt Disney World Village
Orlando, Florida

The American Society of Neuroimaging is pleased to announce tha their 14th Annual Meeting will be held February 5-10, 1991, at the Hilton at Walt Disney World Village, Orlando, Florida.

The major emphasis of the meeting will be on the latest advance in the science of neuroimaging. The Education Program is designed for the clinical practice of neurology and for residents. This includes both basic and advanced programs with certification examinations. A special hands-on Transcranial Doppler Workshop will be featured. Due to heavy demand, early registration for eduational courses is requested. Make plans n to attend.

MEETING SCHEDULE

uesday, February 5, 1991

loming	
8:00-12:00	Basic Ultrasound
8:00-12:00	Applied MRI Physics for Technologists, Basic Scientists and Physicians
fternoon	
2:00- 6:00	Basic Ultrasound
2:00- 6:00	Applied MRI Physics for Technologists, Basic Scientists and Physicians
vening	
5:00- 7:30	Cocktail Reception
7:00-10:00	Hands-On Workshop: Neurosonology

ednesday, February 6, 1991

orning	
3:30- 8:00	Technical Exhibits and Scientific Posters
:45- 8:45	Breakfast Seminar: Laboratory Management/Chair: J. Toole
:00-12:30	Advanced Ultrasound
temoon	
:00- 6:00	Clinical MRI: Brain/Co-Chairs: I. Polachini, A. Carr
ening	
:00- 8:00	Exhibits & Poster Stand-by/Wine and Cheese Reception

Thursday, February 7, 1991

Morning	
8:30- 5:30	Technical Exhibits and Scientific Po
6:45- 8:45	Breakfast Seminar: Case Studies in Neuroimaging/Chair: I. Polachini
9:00-12:30	Clinical MRI: Brain
Afternoon	
2:00- 6:00	Clinical MRI: Spine
Evening	
6:00-11:00	Banquet: Cook-Out

Friday, February 8, 1991

Morning	
6:45- 8:45	Breakfast Seminar: SPECT & PET/ Masdeu
9:00-11:00	Advanced Ultrasound
11:00-12:30	Awards and Business Meeting
Afternoon	
2:00- 6:00	Advanced Topics in Magnetic Reson

Saturday, February 9, 1991

Morning	
6:45- 7:45	Breakfast Seminar: Magnetic Encepholography/Chair: W. McKin
8:00- 1:00	Interventional Neuroimaging/Chairs: Prockop, R. Smith
Afternoon	
2:00- 6:00	Certification Examinations

Sunday, February 10, 1991

Athletic Events

CENTRAL LIBRARY

The Downstate Headache Center

presents the
Third Annual Symposium on

Treatment of Headaches and Facial Pain

Sunday, May 5, 1991
at the Halloran House, New York, NY

Downstate Headache Center Faculty:	Guest Faculty:
Ronald Burakoff, DDS	Joel Saper, MD
Baruch Fishman, PhD	Glen Solomon, MD
Richard Lechtenberg, MD	Seymour Solomon, MD
Alexander Mauskop, MD	

For more information call: 718 935-9666 or write to:
Alexander Mauskop, MD, Director, Downstate Headache Center
132 Atlantic Avenue, Brooklyn Heights, NY 11201

This program is approved for 7 CME credits.

The American Academy of Clinical Neurophysiology's

6th Annual Meeting

will be held at The Westin Hotel, Boston, Massachusetts

June 20 - 23, 1991

President and Founder - Bhagwan T. Shahani, M.D., D. Phil. (Oxon)

The program includes Special Lectures, Symposia, Lunch Sessions and Workshops. Some featured speakers will be: M. Aminoff, A. Beric, I. Bodis-Wollner, G. Celesia, K. Chiappa, G. Comi, J. Desmedt, A. Eisen, D. Ingram, J. Kimura, G. Kraft, A. Sumner, S. Waxman.

A one-day Basic Electromyography course will be held on June 23. Exhibit and poster dates are set for June 21 and 22 with poster presentation date on June 21.

For membership information, meeting details or abstract forms write:

Marlene Richard Fairbanks; Massachusetts General Hospital;
Clinical Neurophysiology Lab; Boston, Massachusetts 02114 or
Fax request for information to 617-726-2019. Tele. 617-726-8736.

A COMPREHENSIVE REVIEW OF
MOVEMENT DISORDERS
FOR THE CLINICAL PRACTITIONER

at the Hotel Jerome, Aspen, Colorado

August 4–7, 1991

Featuring:
Sixteen hours of lectures and videotape demonstrations
over four days in the Rocky Mountains.

FACULTY

STANLEY FAHN, M.D.
H. Houston Merritt
Professor of Neurology
Columbia University
College of Physicians & Surgeons
New York, New York

C. DAVID MARSDEN, D.Sc.
Professor & Head
Department of Clinical Neurology
The National Hospital
London, England

JOSEPH JANKOVIC, M.D.
Professor of Neurology
Baylor College of Medicine
Houston, Texas

Physicians: $425; Fellows & Residents in training: $250.
Tuition fee includes a syllabus, continental breakfasts and refreshments.

Approved for 16 Credit Hours in Category 1, A.M.A.'s Physician's Recognition Award.

Topics (Partial List)

Chorea, Dystonia, Gait Disorders, Myoclonus, Parkinson's Disease, Parkinson-Plus Syndromes, Psychogenic Movement Disorders, Tardive Dyskinesia Syndromes, Tics, Tremors

Recreational Activities Available

Aspen Music Festival, Balloon Rides, Fly-Fishing, Golf, Hiking, Horseback Riding, Swimming, Tennis, White-Water Rafting

of this advertisement.

A CASE FOR *Magnevist*®
(gadopentetate dimeglumine 469.01 mg/mL)
INJECTION

THE CASE: Four years after a radical mastectomy and chemotherapy treatment for breast carcinoma, a 63-year-old female presented with deep vein thrombosis. Metastatic spread to the brain had to be ruled out before anticoagulation therapy could be initiated.

CT DID NOT SHOW IT CLEARLY ENOUGH

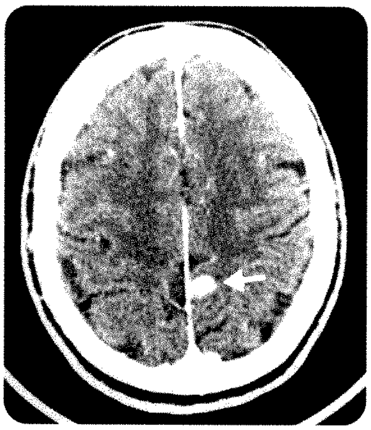

Figure 1. Contrast CT scan shows a circumscribed lesion in left parasagittal region (arrow), consistent with either metastasis or meningioma.

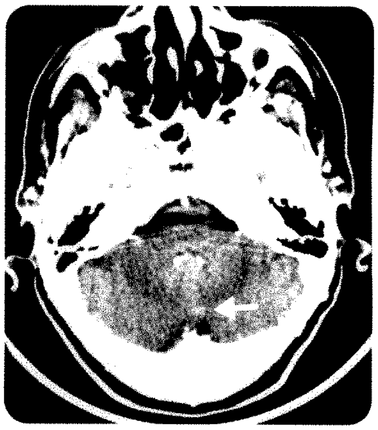

Figure 2. Contrast CT scan through posterior fossa suggests punctate area of contrast uptake in the vermis (arrow).

MRI ALONE WAS NOT DIAGNOSTIC

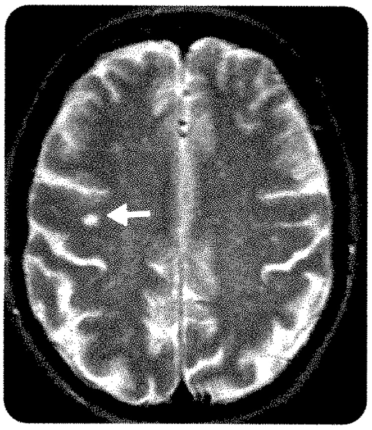

Figure 3. T2-weighted (TR 2000/TE 80) image shows area of high signal intensity in right frontoparietal region (arrow). Differential considerations include metastasis, small infarct, and demyelination. The lesion in left parasagittal region, seen in Figure 1, is not visualized.

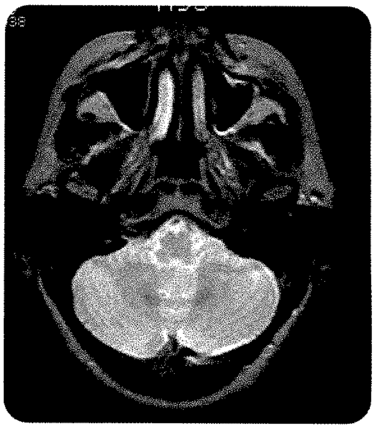

Figure 4. T2-weighted (TR 2000/TE 80) image through posterior fossa shows no abnormalities.

MAGNEVIST® INJECTION: A CRITICAL STEP IN DETECTING BRAIN METASTASES

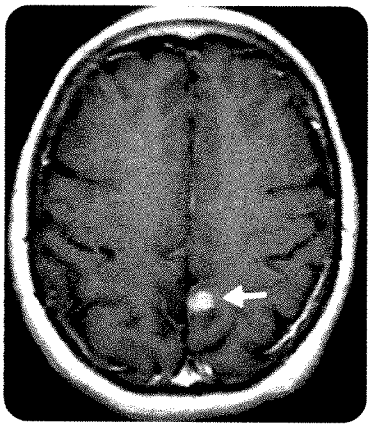

Figure 5. T1-weighted (TR 600/TE 30) image after MAGNEVIST® injection shows an enhancing lesion in left parasagittal region (arrow), as in Figure 1. The high-signal intensity lesion seen in Figure 3 does not enhance. This finding is consistent with chronic small-vessel ischemic disease, not with metastatic disease.

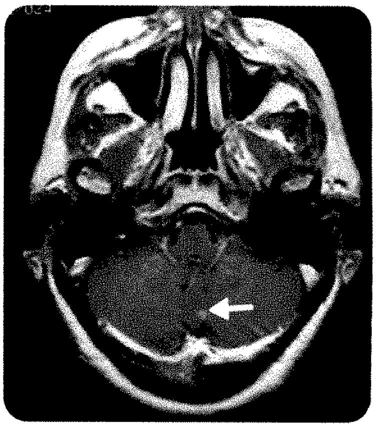

Figure 6. T1-weighted (TR 600/TE 30) enhanced image taken through posterior fossa shows well-delineated lesion in the inferior aspect of the vermis (arrow). Lesion was not clearly appreciated on unenhanced MRI or contrast CT studies.

© 1990, Berlex Laboratories, Inc.
All rights reserved.

☐ **INCREASES DETECTION OF INTRACRANIAL LESIONS**

May detect additional and often smaller lesions than seen with either contrast-enhanced CT or unenhanced T2-weighted images[1,2]

☐ **DETECTION OF ADDITIONAL LESIONS MAY ALTER THERAPY**

MAGNEVIST® injection can increase the radiologic suspicion of metastatic disease, reveal locations more favorable for biopsy, prompt the search for a primary tumor, and modify therapeutic objectives and methods[3]

(gadopentetate dimeglumine 469.01 mg/mL)

INJECTION

BETTER MEDICINE THROUGH BETTER IMAGES

BERLEX

IMAGING

Please see brief summary of prescribing information for MAGNEVIST® injection on last page of this advertisement.

Well tolerated[4] In clinical trials, the most common adverse reactions reported were headache (8.7%) and injection-site coldness/localized coldness (4.8%). The majority of headaches were transient and of mild to moderate severity. In clinical trials, 15% to 30% of patients experienced an asymptomatic transient rise in serum iron; hypotension and anaphylactoid reactions have occurred in less than 1% of the patients. The safety of MAGNEVIST® injection in patients with hemolytic disorders has not been studied.

BRIEF SUMMARY

INDICATIONS AND USAGE

MAGNEVIST® Injection is indicated for use with magnetic resonance imaging (MRI) in adults and children (2 years of age and older) to provide contrast enhancement in those intracranial lesions with abnormal vascularity or those thought to cause an abnormality in the blood-brain barrier. MAGNEVIST® Injection has been shown to facilitate visualization of intracranial lesions including but not limited to tumors.

MAGNEVIST® Injection is also indicated for use with MRI in adults and children (2 years of age and older) to provide contrast enhancement and facilitate visualization of lesions in the spine and associated tissues. There is, however, only limited clinical experience in children for this indication.

CONTRAINDICATIONS

None known.

WARNINGS

The accepted safety considerations and procedures that are required for magnetic resonance imaging are applicable when MAGNEVIST® Injection is used for contrast enhancement. In addition, deoxygenated sickle erythrocytes have been shown in *in vitro* studies to align perpendicular to a magnetic field which may result in vaso-occlusive complications *in vivo*. The enhancement of magnetic moment by gadopentetate dimeglumine may possibly potentiate sickle erythrocyte alignment. MAGNEVIST® Injection in patients with sickle cell anemia and other hemoglobinopathies has not been studied.

Patients with other hemolytic anemias have not been adequately evaluated following administration of MAGNEVIST® Injection to exclude the possibility of increased hemolysis.

Hypotension may occur in some patients after injection of MAGNEVIST® Injection. In clinical trials two cases were reported and in addition, there was one case of a vasovagal reaction and two cases of pallor with dizziness, sweating and nausea in one and substernal pain and flushing in the other. These were reported within 25 to 85 minutes after injection except for the vasovagal reaction which was described as mild by the patient and occurred after 6-1/2 hours. In a study in normal volunteers one subject experienced syncope after arising from a sitting position two hours after administration of the drug. Although the relationship of gadopentetate dimeglumine to these events is uncertain, patients should be observed for several hours after drug administration.

Magnevist®
(gadopentetate
dimeglumine 469.01 mg/mL)
INJECTION

PRECAUTIONS - General

Diagnostic procedures that involve the use of contrast agents should be carried out under direction of a physician with the prerequisite training and a thorough knowledge of the procedure to be performed.

In a patient with a history of grand mal seizures, MAGNEVIST® Injection was reported to induce such a seizure.

Since gadopentetate dimeglumine is cleared from the body by glomerular filtration, caution should be exercised in patients with severely impaired renal function.

The possibility of a reaction, including serious, life-threatening, fatal, anaphylactoid or cardiovascular reactions or other idiosyncratic reactions should always be considered (see ADVERSE REACTIONS) especially in those patients with a known clinical hypersensitivity.

Animal studies suggest that gadopentetate dimeglumine may alter red cell membrane morphology resulting in a slight degree of extravascular (splenic) hemolysis. In clinical trials 15-30% of the patients experienced an asymptomatic transient rise in serum iron. Serum bilirubin levels were slightly elevated in approximately 3.4% of patients. Levels generally returned to baseline within 24 to 48 hours. Hematocrit and red blood cell count were unaffected and liver enzymes were not elevated in these patients. While the effects of gadopentetate dimeglumine on serum iron and bilirubin have not been associated with clinical manifestations, the effect of the drug in patients with hepatic disease is not known and caution is therefore advised.

When MAGNEVIST® Injection is to be injected using plastic disposable syringes, the contrast medium should be drawn into the syringe and used immediately.

If nondisposable equipment is used, scrupulous care should be taken to prevent residual contamination with traces of cleansing agents.

Repeat Procedures: If in the clinical judgment of the physician sequential or repeat examinations are required, a suitable interval of time between administrations should be observed to allow for normal clearance of the drug from the body.

Information for Patients:

Patients receiving MAGNEVIST® Injection should be instructed to:

1. Inform your physician if you are pregnant or breast feeding.
2. Inform your physician if you have anemia or any diseases that affect red blood cells.

LABORATORY TEST FINDINGS

Transitory changes in serum iron and bilirubin levels have been reported in patients with normal and abnormal liver function (See PRECAUTIONS - General).

CARCINOGENESIS, MUTAGENESIS, AND IMPAIRMENT OF FERTILITY

No animal studies have been performed to evaluate the carcinogenic potential of gadopentetate dimeglumine.

Gadopentetate dimeglumine did not evoke any evidence of mutagenic potential in the Ames test (histidine-dependent *Salmonella typhimurium*) nor in a reverse mutation assay using tryptophan-dependent *Escherichia coli*. Gadopentetate dimeglumine did not induce a positive response in the (C3H 10T1/2) mouse embryo fibroblast cellular transformation assay, nor did it induce unscheduled DNA repair synthesis in primary cultures of rat hepatocytes at concentrations up to 5000 µg/mL. However, the drug did show some evidence of mutagenic potential *in vivo* in the mouse dominant lethal assay at doses of 6 mmol/kg, but did not show any such potential in the mouse and dog micronucleus tests at intravenous doses of 9 mmol/kg and 2.5 mmol/kg, respectively.

The results of a reproductive study in rats showed that gadopentetate dimeglumine when administered in daily doses of 0.1-2.5 mmol/kg, did not cause a significant change in the pregnancy rate in comparison to a control group. However, suppression of body weight gain and food consumption and a decrease in the mean weights of testis and epididymis occurred in male rats at the 2.5 mmol/kg dose. In female rats a decrease in the number of corpora lutea at the 0.1 mmol/kg dose and the suppression of body weight gain and food consumption at the 2.5 mmol/kg dose were observed.

In a separate experiment, 16 daily intravenous injections were administered to male rats. At a dose of 5 mmol/kg of gadopentetate dimeglumine, spermatogenic cell atrophy was observed. This atrophy was not reversed within a 16-day observation period following the discontinuation of the drug. This effect was not observed at a dose of 2.5 mmol/kg.

PREGNANCY CATEGORY C.

Gadopentetate dimeglumine has been shown to retard development slightly in rats when given in doses 2.5 times the human dose, and in rabbits when given in doses of 7.5 and 12.5 times the human dose. The drug did not exhibit this effect in rabbits when given in doses 2.5 times the human dose. No congenital anomalies were noted in either species.

There are no adequate and well-controlled studies in pregnant women. MAGNEVIST® Injection should be used during pregnancy only if the potential benefit justifies the potential risk to the fetus.

NURSING MOTHERS

C^{14} labelled gadopentetate dimeglumine was administered intravenously to lactating rats at a dose of 0.5 mmol/kg. Less than 0.2% of the total dose was transferred to the neonate via the milk during the 24-hour evaluation period. It is not known to what extent MAGNEVIST® Injection is excreted in human milk. Because many drugs are excreted in human milk, caution should be exercised when the drug is administered to a nursing mother and consideration should be given to temporarily discontinuing nursing.

PEDIATRIC USE

Safety and efficacy in children under the age of 2 years have not been established. (See Indications and Usage and Dosage and Administration sections).

ADVERSE REACTIONS

The most commonly noted adverse experience is headache with an incidence of 8.7%. The majority of headaches are transient and of mild to moderate severity. In 42.3% of the cases it was felt that the headaches were not related to MAGNEVIST® Injection. Injection site coldness/localized coldness is the second most common adverse experience at 4.8%. Nausea occurs in 3.2% of the patients.

Localized pain, vomiting, paresthesia, dizziness and localized warmth occur in less than 2% of the patients.

The following additional adverse events occur in less than 1% of the patients:

Body as a Whole: Injection site symptoms, namely, pain, warmth, burning; localized burning sensation, substernal chest pain, fever, weakness, generalized coldness, localized edema, tiredness, chest tightness, regional lymphangitis, anaphylactoid reactions (characterized by cardiovascular, respiratory and cutaneous symptoms).

Cardiovascular: Hypotension, vasodilation, pallor, non-specific ECG changes, angina pectoris, phlebitis.

Digestive: Gastrointestinal distress, stomach pain, teeth pain, increased salivation.

Nervous System: Agitation, thirst, convulsions (including grand mal).

Respiratory System: Throat irritation, rhinorrhea, sneezing, dyspnea, wheezing, laryngismus, cough.

Skin: Rash, sweating, pruritus, urticaria (hives).

Special Senses: Tinnitus, conjunctivitis, visual field defect, taste abnormality, dry mouth, lacrimation disorder (tearing), eye irritation.

Laboratory: Transient elevation of serum transaminases.

The following other adverse events were reported. A causal relationship has neither been established nor refuted.

Body as a Whole: Back pain, pain, generalized warmth.

Cardiovascular: Hypertension, tachycardia, migraine, syncope, death related to myocardial infarction or other undetermined causes.

Digestive: Constipation, diarrhea.

Nervous System: Anxiety, anorexia, nystagmus, drowsiness, diplopia, stupor.

Skin: Facial edema, erythema multiforme, epidermal necrolysis.

Special Senses: Eye pain, ear pain.

Data from foreign studies did not reveal any additional adverse experiences.

OVERDOSAGE

The LD_{50} of intravenously administered gadopentetate dimeglumine injection in mice is 5-12.5 mmol/kg and in rats it is 10-15 mmol/kg. The LD_{50} of intravenously administered MAGNEVIST® Injection in dogs is greater than 6 mmol/kg.

Clinical consequences of overdose with MAGNEVIST® Injection have not been reported.

DOSAGE AND ADMINISTRATION

The recommended dosage of MAGNEVIST® Injection is 0.2 mL/kg (0.1 mmol/kg), administered intravenously, at a rate not to exceed 10 mL per minute. More rapid injection rates may be associated with nausea. The maximum total dose is 20 mL. Any unused portion must be discarded.

DOSAGE CHART

Body Weight (kg)	Dose in mL	Approx Duration of Injection in Seconds
10	2.0	20
20	4.0	30
30	6.0	40
40	8.0	50
50	10.0	60
60	12.0	70
70	14.0	80
80	16.0	95
90	18.0	110
100	20.0	120

To ensure complete injection of the contrast medium, the injection should be followed by a 5-mL normal saline flush. The imaging procedure should be completed within 1 hour of injection of MAGNEVIST® Injection.

Parenteral products should be inspected visually for particulate matter and discoloration prior to administration, whenever solution and container permit.

For full prescribing information, see package insert.

Caution: Federal Law Prohibits Dispensing Without Prescription.

POSTHERPETIC NEURALGIA

There Are Many Words To Describe The Pain.

STABBING
PENETRATING
SHARP
JABBING
SHOOTING
UNBEARABLE
PIERCING
GRIPPING
SEARING

And One For Treating It.

Topical
Zostrix®
(Capsaicin 0.025% w/w) Cream

When patients describe the "hurt" of postherpetic neuralgia (PHN), they use a wide range of words to describe a pain that is often intractable and difficult to treat. Zostrix® (Capsaicin 0.025% w/w) Cream provides an effective topical treatment that alleviates intense pain in most PHN patients.

Topical Zostrix Works Where It Hurts

Zostrix®

(Capsaicin 0.025% w/w) Cream

Topical Analgesic

TARGETED ACTION

Acts on sensory nerves at site of application by selectively depleting substance P, a chemomediator of pain impulses along neuropathways.

EFFECTIVE

Alleviates the intense pain associated with postherpetic neuralgia in most patients. May also benefit patients when added to existing systemic drug regimens.

SAFE

No known interactions with systemic medications commonly prescribed for geriatric patients.

Topical Zostrix Works Where It Hurts

DESCRIPTION

Zostrix Cream contains capsaicin, 0.025% w/w, in an emollient base containing benzyl alcohol, cetyl alcohol, glyceryl monostearate, isopropyl myristate, polyoxyethylene stearate blend, purified water, sorbitol solution and white petrolatum. Capsaicin is a naturally occurring substance derived from plants of the Solanaceae family with the chemical name trans-8-methyl-N-vanillyl-6-nonenamide. Capsaicin is a white crystalline powder with a molecular weight of 305.4. It is practically insoluble in water but very soluble in alcohol, ether and chloroform.

ACTION

Although the precise mechanism of action of capsaicin is not fully understood, current evidence suggests that capsaicin renders skin and joints insensitive to pain by depleting and preventing reaccumulation of substance P in peripheral sensory neurons. Substance P is thought to be the principal chemomediator of pain impulses from the periphery to the central nervous system. In addition, substance P has been shown to be released into joint tissues and activate inflammatory mediators involved with the pathogenesis of rheumatoid arthritis.

INDICATION

Zostrix is indicated for the temporary relief of peripheral neuralgias such as the pain following shingles (herpes zoster). Zostrix is also indicated for the temporary relief of the pain associated with rheumatoid arthritis and osteoarthritis.

WARNINGS

FOR EXTERNAL USE ONLY. Avoid contact with eyes and broken or irritated skin. Do not bandage tightly. If condition worsens, or does not improve after 28 days, discontinue use of this product and consult your physician. **Keep this and all drugs out of the reach of children.** In case of accidental ingestion, seek professional assistance or contact a Poison Control Center immediately.

DIRECTIONS

Adults and children 2 years of age and older: Apply Zostrix to affected area 3 to 4 times daily. Transient burning may occur upon application, but usually disappears in 72 hours. Application schedules of less than 3 to 4 times a day may not provide optimum pain relief and the burning sensation may persist. **Wash hands immediately after applying Zostrix.**

Instructions for Authors

Send manuscripts by first-class mail to the Chief Editor, Robert J. Joynt, MD, PhD, University of Rochester School of Medicine and Dentistry, 601 Elmwood Ave, Rochester, NY 14642. Manuscripts are received with the understanding that they are not under simultaneous consideration by another publication. Accepted manuscripts become the permanent property of the ARCHIVES and may not be published elsewhere without permission from the publisher (AMA).

In addition, in view of *The Copyright Revision Act of 1976*, effective Jan 1, 1978, transmittal letters to the editor should contain the following language: "In consideration of the American Medical Association's taking action in reviewing and editing my submission, the author(s) undersigned hereby transfers, assigns, or otherwise conveys all copyright ownership to the AMA in the event that such work is published by the AMA." We regret that transmittal letters not containing the foregoing language signed by all authors of the submission will necessitate delay in review of the manuscript.

Author Responsibility.—All accepted manuscripts are subject to copy editing. The author will receive an edited typescript rather than galley proofs for approval. The author is responsible for all statements in his work, including changes made by the copy editor.

Designate one author as correspondent and provide his address and telephone number. Order reprints at the time the typescript is returned after editorial processing. Specify address to which requests for reprints should be sent.

Manuscript Preparation.—Submit three high-quality copies of the entire manuscript. The copies will not be returned. The authors should keep the original manuscript for submission if accepted. The original manuscript (including references, legends, and tables) must be typed double-spaced on 21.6 × 27.9-cm 8½ × 11-in), heavy-duty white bond paper. Ample margins of at least 2.5 cm (1 in) should be provided. **If a word processor is used, do not justify right-hand margins.**

Refer to patients by number (or, in anecdotal reports, by fictitious given names). Real names or initials should not be used in the text, tables, or illustrations.

Titles.—Titles should be short, specific, and clear. They should not exceed 42 characters per line, including punctuation and spaces, and be limited to two lines, if possible. The title page should include the full names and academic affiliations of all authors, the address to which requests for reprints should be sent, and, if the manuscript was presented at a meeting, the name of the organization, place, and date on which it was read.

Style of Writing.—The style of writing should conform to acceptable English usage and syntax. Slang, medical jargon, obscure abbreviations, and abbreviated phrasing are to be avoided.

Informed Consent.—Manuscripts reporting the results of experimental investigations of human subjects must include a statement to the effect that informed consent was obtained after the nature of the procedure(s) had been fully explained.

Abstract.—Provide an abstract (135-word maximum) of the article, including statements of the problem, method of study, results, and conclusions. The abstract replaces the summary.

References.—List references in consecutive numerical order (not alphabetically). Once a reference is cited, all subsequent citations should be to the original number. All references must be cited in the text or tables. Unpublished data and personal communications should not be listed as references. References to journal articles should include (1) author(s) (list all authors and/or editors up to six; if more than six, list the first three and "et al"), (2) title, (3) journal name (as abbreviated in *Index Medicus*), (4) year, (5) volume number, and (6) inclusive page numbers, in that order. References to books should include (1) author(s) (list all authors and/or editors up to six; if more than six, list the first three and "et al"), (2) chapter title (if any), (3) editor (if any), (4) title of book, (5) city of publication, (6) publisher, and (7) year. Volume and edition numbers, specific pages, and name of translator should be included when appropriate. **The author is responsible for the accuracy and completeness of the references and for their correct text citation.**

SI Units.—Use Système International (SI) measurements throughout the manuscript. (See June 1986 issue of the ARCHIVES.)

Illustrations.—The illustrations originally submitted will not be returned. High-quality copies may be used. Original illustrations should be kept by the author for submission if the manuscript is accepted. Use only those illustrations that clarify and augment the text. If accepted, submit illustrations in triplicate, unmounted and untrimmed. Do not send original artwork. Send high-contrast glossy prints (not photocopies). Figure number, name of senior author, and arrow indicating "top" should be typed on a gummed label and affixed to the back of each illustration. All lettering must be legible after reduction to column size. Artwork submitted for publication may be relettered to achieve uniformity of lettering style throughout the journal. Magnification and stain should be provided when pertinent. Illustrations should preferably be in a proportion of 12.7 × 7.3 cm (5 × 7 in).

An experienced medical illustrator should be employed whenever possible for the preparation of all artwork. Template lettering or preset type is preferred to hand-lettered labels. If halftone artwork with labels is submitted, affix type and leaders to a clear acetate overlay registered to the base drawing. Labels and leaders should be applied directly to the drawing board surface if the artwork consists only of line ink technique.

Illustrations in full color are accepted for publication if the editors believe that color will add significantly to the published manuscript. The ARCHIVES will pay part of the expense of reproduction and printing color illustrations, the remainder to be borne by the author or his sponsor. After deducting the ARCHIVES' contribution, the author's share is $400 for up to six square-finished illustrations that can be arranged on a one-page layout. Any additional illustrations or special effects will be billed to the author at cost. Positive color transparencies (35 mm preferred) must be submitted for an evaluation. Do not send color prints unless accompanied by original transparencies. All transparencies should be carefully packed and sent with the manuscript.

Legends.—Legends should be typed double-spaced, beginning on a separate sheet of paper. Length should be limited to a maximum of 40 words.

Photographic Consents.—A letter of consent must accompany all photographs of patients in which a possibility of identification exists. It is not sufficient to cover the eyes to mask identity.

Acknowledgments.—Illustrations from other publications must be acknowledged. Include the following when applicable: author(s), title of article, title of journal or book, volume number, page(s), month, and year. The publisher's permission to reprint should be submitted to the ARCHIVES after the manuscript has been formally accepted.

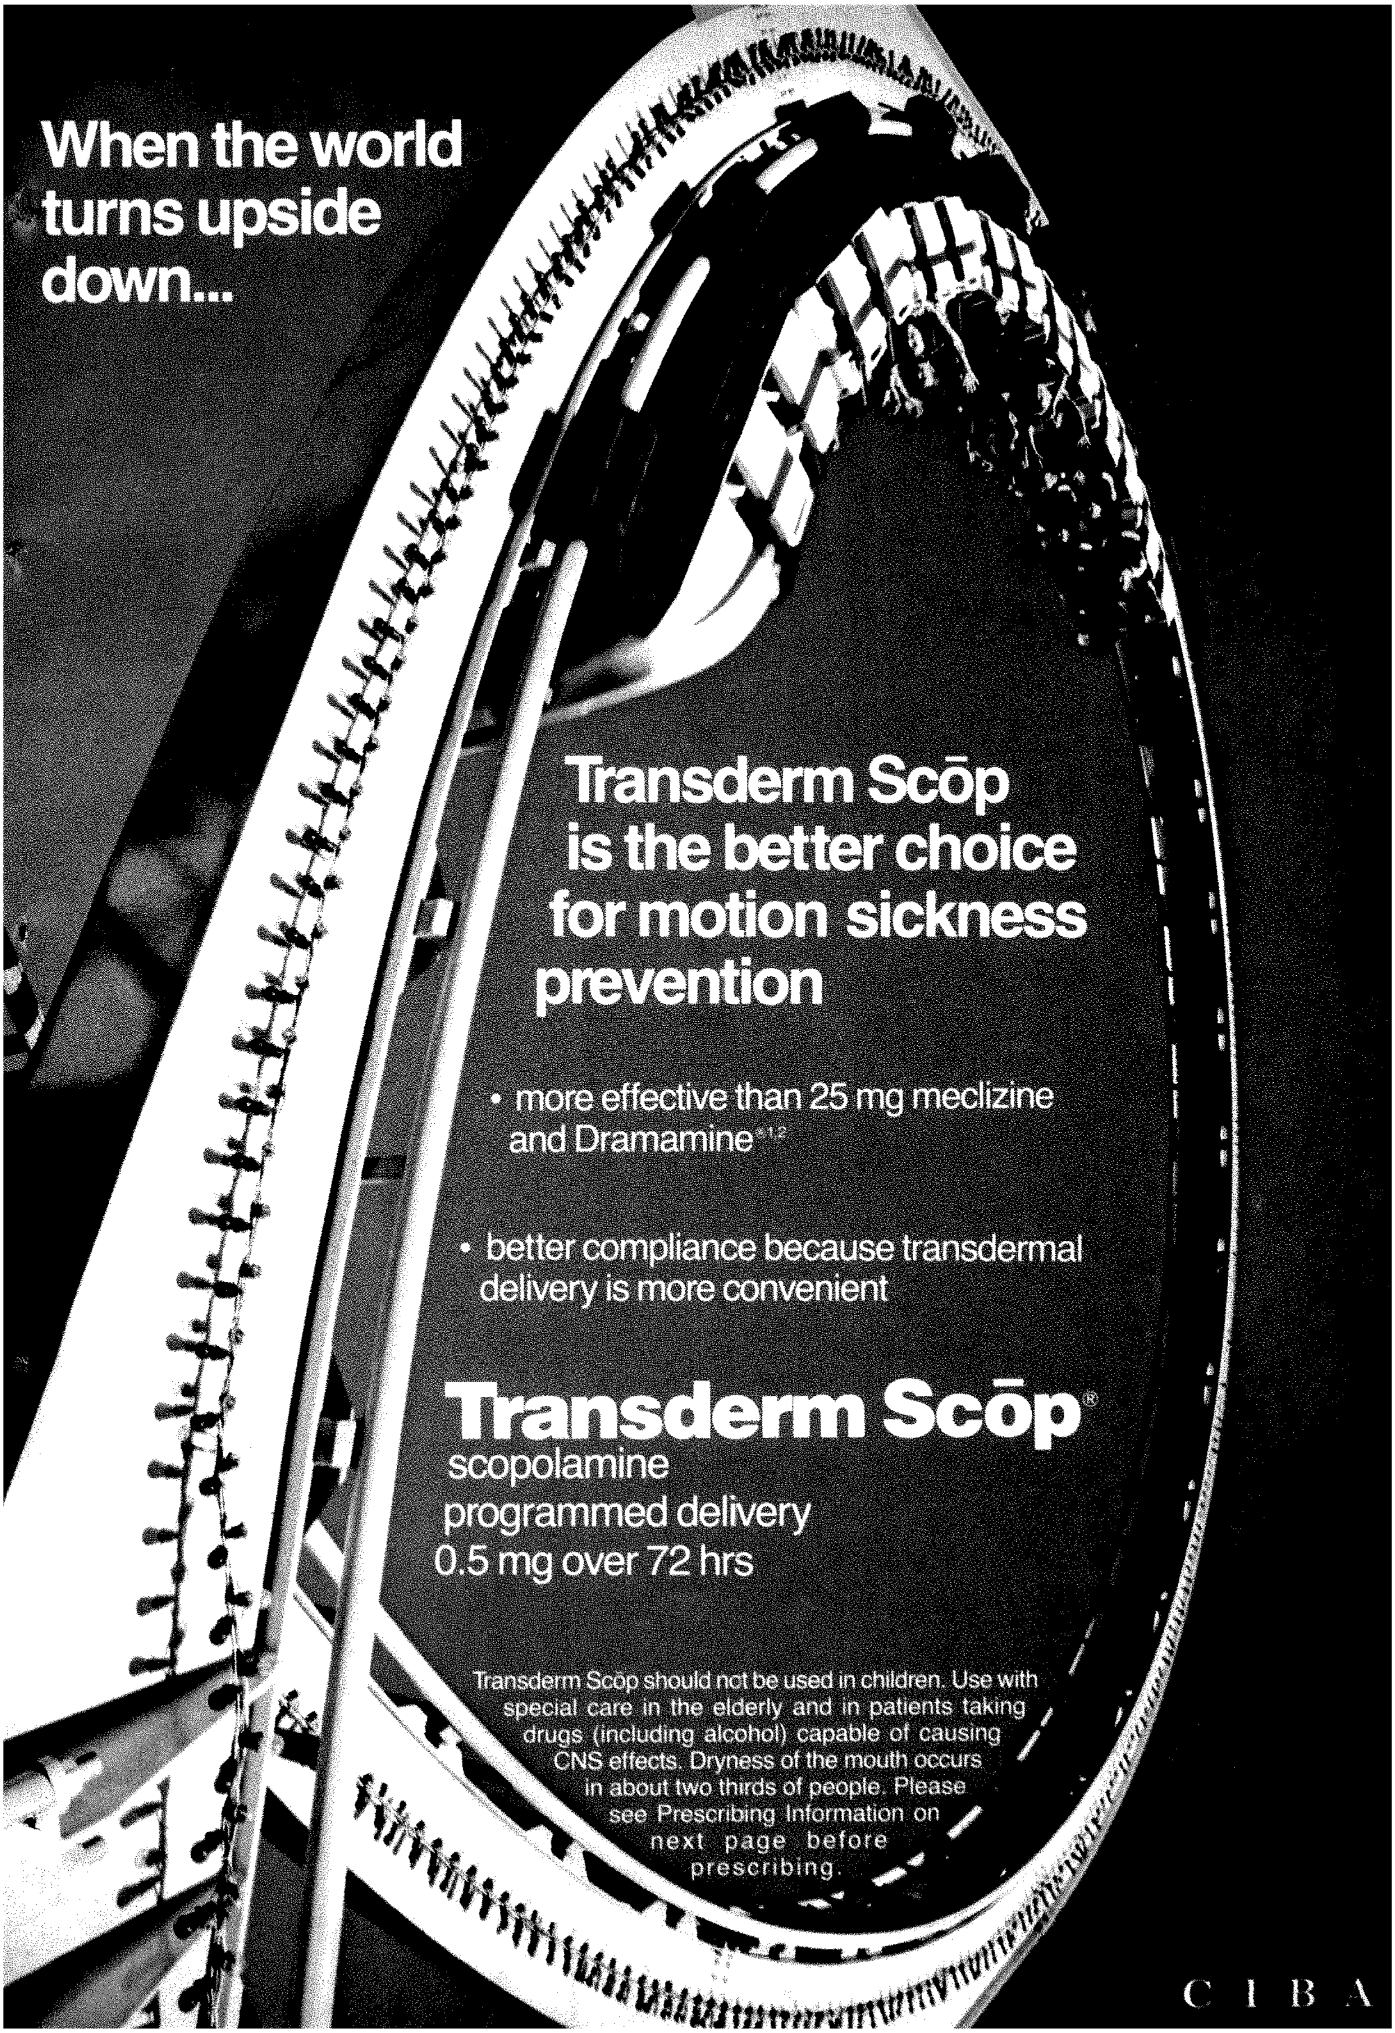
Statistical Review.—Manuscripts containing statistical evaluations should include the name and affiliation of the statistical reviewer.

Tables.—Each table should be typed double-spaced, including all headings, on a separate sheet of 21.6 × 27.9-cm (8½ × 11-in) paper. Do not use larger size paper. If a table must be continued, use a second sheet and repeat all heads and stubs. Each table must have a title.

Financial Disclosure.—In the cover letter, list all affiliations with, or financial involvement in, organizations or entities with a direct financial interest in the subject matter or material of the research discussed in the manuscript (eg, employment consultancies, stock ownership). All such information will be held in confidence during the review process. Should the manuscript be accepted, the Chief Editor will discuss with the author the extent of disclosures appropriate for publication.

AMA Manual of Style.—This 1988 edition, formerly the *Manual for Authors & Editors*, is available from Williams & Wilkins, 428 E Preston St, Baltimore, MD 21202. Single copy price: $26.95. A shipping charge is added on all orders not prepaid. If additional ordering information is needed, or to order by telephone, call 1-800-638-0672.

Proprietary Statement.—If the article discusses in any way a device, equipment, instrument, or drug, the author(s) must state in a footnote whether they do or do not have any commercial or proprietary interest in the product. Likewise, they must reveal whether they have any financial interest as a consultant, reviewer, or evaluator. In addition, authors must disclose any financial interest owned by a spouse, minor child, blood-relative living in the same household, or known to be held by the author's employer or partner.



When the world turns upside down...

Transderm Scōp is the better choice for motion sickness prevention

- more effective than 25 mg meclizine and Dramamine®[1,2]
- better compliance because transdermal delivery is more convenient

Transderm Scōp®
scopolamine
programmed delivery
0.5 mg over 72 hrs

Transderm Scōp should not be used in children. Use with special care in the elderly and in patients taking drugs (including alcohol) capable of causing CNS effects. Dryness of the mouth occurs in about two thirds of people. Please see Prescribing Information on next page before prescribing.

CIBA

Transderm Scōp®

scopolamine

(formerly Transderm-V)

Transdermal Therapeutic System

Programmed delivery *in vivo* of 0.5 mg of scopolamine over 3 days

BRIEF SUMMARY (FOR FULL PRESCRIBING INFORMATION, SEE PACKAGE INSERT)

INDICATIONS AND USAGE

Transderm Scōp is indicated for prevention of nausea and vomiting associated with motion sickness in adults. The disc should be applied only to skin in the postauricular area.

Clinical Results: Transderm Scōp provides antiemetic protection within several hours following application of the disc behind the ear. In 195 adult subjects of different racial origins who participated in clinical efficacy studies at sea or in a controlled motion environment, there was a 75% reduction in the incidence of motion-induced nausea and vomiting. Transderm Scōp provided significantly greater protection than that obtained with oral dimenhydrinate.

CONTRAINDICATIONS

Transderm Scōp should not be used in patients with known hypersensitivity to scopolamine or any of the components of the adhesive matrix making up the therapeutic system, or in patients with glaucoma.

WARNINGS

Transderm Scōp should not be used in children and should be used with special caution in the elderly. See **PRECAUTIONS.**

Since drowsiness, disorientation, and confusion may occur with the use of scopolamine, patients should be warned of the possibility and cautioned against engaging in activities that require mental alertness, such as driving a motor vehicle or operating dangerous machinery.

Potentially alarming idiosyncratic reactions may occur with ordinary therapeutic doses of scopolamine.

PRECAUTIONS

General

Scopolamine should be used with caution in patients with pyloric obstruction, or urinary bladder neck obstruction. Caution should be exercised when administering an antiemetic or antimuscarinic drug to patients suspected of having intestinal obstruction.

Transderm Scōp should be used with special caution in the elderly or in individuals with impaired metabolic, liver, or kidney functions, because of the increased likelihood of CNS effects.

Information for Patients

Since scopolamine can cause temporary dilation of the pupils and blurred vision if it comes in contact with the eyes, patients should be strongly advised to wash their hands thoroughly with soap and water immediately after handling the disc.

Patients should be advised to remove the disc immediately and contact a physician in the unlikely event that they experience symptoms of acute narrow-angle glaucoma (pain in and reddening of the eyes accompanied by dilated pupils).

Patients should be warned against driving a motor vehicle or operating dangerous machinery. A patient brochure is available.

Drug Interactions

Scopolamine should be used with care in patients taking drugs, including alcohol, capable of causing CNS effects. Special attention should be given to drugs having anticholinergic properties, e.g., belladonna alkaloids, antihistamines (including meclizine), and antidepressants.

Carcinogenesis, Mutagenesis, Impairment of Fertility

No long-term studies in animals have been performed to evaluate carcinogenic potential. Fertility studies were performed in female rats and revealed no evidence of impaired fertility or harm to the fetus due to scopolamine hydrobromide administered by daily subcutaneous injection. In the highest-dose group (plasma level approximately 500 times the level achieved in humans using a transdermal system), reduced maternal body weights were observed.

Pregnancy Category C

Teratogenic studies were performed in pregnant rats and rabbits with scopolamine hydrobromide administered by daily intravenous injection. No adverse effects were recorded in the rats. In the rabbits, the highest dose (plasma level approximately 100 times the level achieved in humans using a transdermal system) of drug administered had a marginal embryotoxic effect. Transderm Scōp should be used during pregnancy only if the anticipated benefit justifies the potential risk to the fetus.

Nursing Mothers

It is not known whether scopolamine is excreted in human milk. Because many drugs are excreted in human milk, caution should be exercised when Transderm Scōp is administered to a nursing woman.

Pediatric Use

Children are particularly susceptible to the side effects of belladonna alkaloids. Transderm Scōp should not be used in children because it is not known whether this system will release an amount of scopolamine that could produce serious adverse effects in children.

ADVERSE REACTIONS

The most frequent adverse reaction to Transderm Scōp is dryness of the mouth. This occurs in about two thirds of the people. A less frequent adverse reaction is drowsiness, which occurs in less than one sixth of the people. Transient impairment of eye accommodation, including blurred vision and dilation of the pupils, is also observed.

The following adverse reactions have also been reported on infrequent occasions during the use of Transderm Scōp: disorientation; memory disturbances; dizziness; restlessness; hallucinations; confusion; difficulty urinating; rashes and erythema; acute narrow-angle glaucoma; and dry, itchy, or red eyes.

Drug Withdrawal: Symptoms including dizziness, nausea, vomiting, headache and disturbances of equilibrium have been reported in a few patients following discontinuation of the use of the Transderm Scōp system. These symptoms have occurred most often in patients who have used the systems for more than three days.

OVERDOSAGE

Overdosage with scopolamine may cause disorientation, memory disturbances, dizziness, restlessness, hallucinations, or confusion. Should these symptoms occur, the Transderm Scōp disc should be immediately removed. Appropriate parasympathomimetic therapy should be initiated if these symptoms are severe.

DOSAGE AND ADMINISTRATION

Initiation of Therapy: One Transderm Scōp disc (programmed to deliver 0.5 mg of scopolamine over 3 days) should be applied to the hairless area behind one ear at least 4 hours before the antiemetic effect is required. Only one disc should be worn at any time.

Handling: *After the disc is applied on dry skin behind the ear, the hands should be washed thoroughly with soap and water and dried. Upon removal of the disc, it should be discarded, and the hands and application site washed thoroughly with soap and water and dried, to prevent any traces of scopolamine from coming into direct contact with the eyes. (A patient brochure is available.)*

Continuation of Therapy: Should the disc become displaced, it should be discarded, and a fresh one placed on the hairless area behind the other ear. If therapy is required for longer than 3 days, the first disc should be discarded, and a fresh one placed on the hairless area behind the other ear.

The system should be stored between 59°-86°F (15°-30°C).

CAUTION

Federal law prohibits dispensing without prescription.

PERMAX®

pergolide mesylate

An added dimension
in the treatment of
Parkinson's disease

An adjunct to levodopa/carbidopa in the management of patients with Parkinson's disease

- The first dopamine agonist indicated for Parkinson's disease with activity at both D_1 and D_2 receptors
- 10 to 1,000 times more potent than bromocriptine on a milligram-per-milligram basis
- Improves patients' functioning in activities of daily living, relieves signs and symptoms, and reduces "off" time
- May allow a significant reduction in levodopa dosage
- Most common adverse events were dyskinesia, nausea, dizziness, and hallucinations
- Hypotension may occur, especially early in the course of therapy
- Stepwise titration without regard to meals
- Available in 0.05-mg, 0.25-mg, and 1-mg scored tablets

See adjacent page for prescribing information.

Permax*

pergolide mesylate

Brief Summary. Consult the package insert for complete prescribing information.

Indications and Usage: Permax is indicated as adjunctive treatment to levodopa/carbidopa in the management of the signs and symptoms of Parkinson's disease.

Evidence to support the efficacy of pergolide mesylate as an antiparkinsonian adjunct was obtained in a multicenter study enrolling 376 patients with mild to moderate Parkinson's disease who were intolerant to levodopa/carbidopa as manifested by moderate to severe dyskinesia and/or on-off phenomena. On average, the sample of patients evaluated had been on levodopa/carbidopa for 3.9 years (range, two days to 16.8 years). The administration of pergolide mesylate permitted a 5% to 30% reduction in the daily dose of levodopa. On average, these patients treated with pergolide mesylate maintained an equivalent or better clinical status than they exhibited at baseline.

Contraindications: Pergolide mesylate is contraindicated in patients who are hypersensitive to this drug or other ergot derivatives.

Warnings: *Symptomatic Hypotension* —In clinical trials, approximately 10% of patients taking pergolide mesylate with levodopa vs 7% taking placebo with levodopa experienced symptomatic orthostatic and/or sustained hypotension, especially during initial treatment. With gradual dosage titration, tolerance to the hypotension usually develops. It is, therefore, important to warn patients of the risk, to begin therapy with low doses, and to increase the dosage in carefully adjusted increments over a period of three to four weeks.

Hallucinosis —In controlled trials, pergolide mesylate with levodopa caused hallucinosis in about 14% of patients as opposed to 3% taking placebo with levodopa. This was of sufficient severity to cause discontinuation of treatment in about 3% of those enrolled; tolerance to this untoward effect was not observed.

Fatalities —In the placebo-controlled trial, two of 187 patients treated with placebo died as compared with one of 189 patients treated with pergolide mesylate. Of the 2,299 patients treated with pergolide mesylate in premarketing studies evaluated as of October 1988, 143 died while on the drug or shortly after discontinuing the drug. The patient population under evaluation was elderly, ill, and at high risk for death. It seems unlikely that pergolide mesylate played any role in these deaths, but the possibility that pergolide shortens survival of patients cannot be excluded with absolute certainty.

In particular, a case-by-case review of the clinical course of the patients who died failed to disclose any unique set of signs, symptoms, or laboratory results that would suggest that treatment with pergolide caused their deaths. Sixty-eight percent (68%) of the patients who died were 65 years of age or over. No death (other than a suicide) occurred within the first month of treatment; most of the patients who died had been on pergolide for years. A relative frequency of the causes of death by organ system are: pulmonary failure/pneumonia, 35%; cardiovascular, 30%; cancer, 11%; unknown, 8.4%; infection, 3.5%; extrapyramidal syndrome, 3.5%; stroke, 2.1%; dysphagia, 2.1%; injury, 1.4%; suicide, 1.4%; dehydration, 0.7%; glomerulonephritis, 0.7%.

Precautions: *General* —Caution should be exercised when administering pergolide mesylate to patients prone to cardiac dysrhythmias.

In a study comparing pergolide mesylate and placebo, patients taking pergolide mesylate were found to have significantly more episodes of atrial premature contractions (APCs) and sinus tachycardia.

The use of pergolide mesylate in patients on levodopa may cause and/or exacerbate preexisting states of confusion and hallucinations (*see* Warnings). Also, the abrupt discontinuation of pergolide mesylate in patients receiving it chronically as an adjunct to levodopa may precipitate the onset of hallucinations and confusion; these may occur within a span of several days. Discontinuation of pergolide should be undertaken gradually whenever possible, even if the patient is to remain on levodopa.

The administration of pergolide mesylate to patients receiving levodopa may cause and/or exacerbate preexisting dyskinesia.

Information for Patients —Patients and their families should be informed of the common adverse consequences of the use of pergolide mesylate (*see* Adverse Reactions) and the risk of hypotension (*see* Warnings).

Patients should be advised to notify their physician if they become pregnant or intend to become pregnant during therapy.

Patients should be advised to notify their physician if they are breast feeding an infant.

Laboratory Tests —No specific laboratory tests are deemed essential for the management of patients on Permax. Periodic routine evaluation of all patients, however, is appropriate.

Drug Interactions —Dopamine antagonists, such as the neuroleptics (phenothiazines, butyrophenones, thioxanthines) or metoclopramide, ordinarily should not be administered concurrently with Permax (a dopamine agonist); these agents may diminish the effectiveness of Permax.

Because pergolide mesylate is approximately 90% associated with plasma proteins, caution should be exercised if pergolide mesylate is coadministered with other drugs known to affect protein binding.

Carcinogenesis, Mutagenesis, and Impairment of Fertility —A two-year carcinogenicity study was conducted in mice using dietary levels of pergolide mesylate equivalent to oral doses of 0.6, 3.7, and 36.4 mg/kg/day in males and 0.6, 4.4, and 40.8 mg/kg/day in females. A two-year study in rats was conducted using dietary levels equivalent to oral doses of 0.04, 0.18, and 0.88 mg/kg/day in males and 0.05, 0.28, and 1.42 mg/kg/day in females. The highest doses tested in the mice and rats were approximately 340 and 12 times the maximum human oral dose administered in controlled clinical trials (6 mg/day equivalent to 0.12 mg/kg/day).

A low incidence of uterine neoplasms occurred in both rats and mice. Endometrial adenomas and carcinomas were observed in rats. Endometrial sarcomas were observed in mice. The occurrence of these neoplasms is probably attributable to the high estrogen/progesterone ratio which would occur in rodents as a result of the prolactin-inhibiting action of pergolide mesylate. The endocrine mechanisms believed to be involved in the rodents are not present in humans. However, even though there is no known correlation between uterine malignancies occurring in pergolide-treated rodents and human risk, there are no human data to substantiate this conclusion.

Pergolide mesylate was evaluated for mutagenic potential in a battery of tests that included an Ames bacterial mutation assay, a DNA repair assay in cultured rat hepatocytes, a point-mutation assay in cultured L5178Y cells, and a determination of chromosome alteration in bone marrow cells of Chinese hamsters. A weak mutagenic response was noted in the in vitro mammalian cell-point-mutation assay using L5178Y cells only after metabolic activation with rat liver microsomes. No mutagenic effects were obtained in the two other in vitro assays and in the in vivo assay. The relevance of these findings to humans is unknown.

A fertility study in male and female mice showed that fertility was maintained at 0.6 and 1.7 mg/kg/day but decreased at 5.6 mg/kg/day. Prolactin has been reported to be involved in stimulating and maintaining progesterone levels required for implantation in mice and, therefore, the impaired fertility at high dose may occur because of depressed prolactin levels.

Usage in Pregnancy—Pregnancy Category B —Reproduction studies were conducted in mice at doses of 5, 16, and 45 mg/kg/day and in rabbits at doses of 2, 6, and 16 mg/kg/day. The highest doses tested in mice and rabbits were 375 and 133 times the 6 mg/day maximum human dose administered in controlled clinical trials. In these studies, there was no evidence of harm to the fetus due to pergolide mesylate.

There are, however, no adequate and well-controlled studies in pregnant women. Among women who received pergolide mesylate for endocrine disorders in premarketing studies, there were 33 pregnancies that resulted in healthy babies and four pregnancies that resulted in congenital abnormalities (two major, two minor); a causal relationship has not been established. Because human data are limited and because animal reproduction studies are not always predictive of human response, this drug should be used during pregnancy only if clearly needed.

Nursing Mothers —It is not known whether this drug is excreted in human milk. The pharmacologic action of pergolide mesylate suggests that it may interfere with lactation. Because many drugs are excreted in human milk and because of the potential for serious adverse reactions to pergolide mesylate in nursing infants, a decision should be made whether to discontinue nursing or to discontinue the drug, taking into account the importance of the drug to the mother.

Pediatric Use —Safety and effectiveness in children have not been established.

Adverse Reactions: *Commonly Observed* —In premarketing clinical trials, the most commonly observed adverse events associated with use of pergolide mesylate which were not seen at an equivalent incidence among placebo-treated patients were: nervous system complaints, including dyskinesia, hallucinations, somnolence, insomnia; digestive complaints, including nausea, constipation, diarrhea, dyspepsia; and respiratory system complaints, including rhinitis.

Associated With Discontinuation of Treatment —Twenty-seven percent (27%) of approximately 1,200 patients receiving pergolide mesylate for treatment of Parkinson's disease in premarketing clinical trials in the US and Canada discontinued treatment due to adverse events. The events most commonly causing discontinuation were related to the nervous system (15.5%), primarily hallucinations (7.8%) and confusion (1.8%).

Fatalities - *See* Warnings.

Incidence in Controlled Clinical Trials —The table that follows enumerates adverse events that occurred at a frequency of 1% or more among patients taking pergolide mesylate who participated in the premarketing controlled clinical trials comparing pergolide mesylate with placebo. In a double-blind, controlled study of six months' duration, patients with Parkinson's disease were continued on levodopa/carbidopa and were randomly assigned to receive either pergolide mesylate or placebo as additional therapy.

The prescriber should be aware that these figures cannot be used to predict the incidence of side effects in the course of usual medical practice where patient characteristics and other factors differ from those which prevailed in the clinical trials. Similarly, the cited frequencies cannot be compared with figures obtained from other clinical investigations involving different treatments, uses, and investigators. The cited figures, however, do provide the prescribing physician with some basis for estimating the relative contribution of drug and nondrug factors to the side-effect incidence rate in the population studied.

Incidence of Treatment-Emergent Adverse Experiences in the Placebo-Controlled Clinical Trial

	Percentage of Patients Reporting Events

*Events reported by at least 1% of patients receiving pergolide mesylat
included.

Events Observed During the Premarketing Evaluation of Permax —Th
tion reports event frequencies evaluated as of October 1988 for adverse
ocurring in a group of approximately 1,800 patients who took multiple d
pergolide mesylate. The conditions and duration of exposure to pe
mesylate varied greatly, involving well-controlled studies as well as exp
in open and uncontrolled clinical settings. In the absence of appropria
trols in some of the studies, a causal relationship between these ever
treatment with pergolide mesylate cannot be determined.

The following enumeration by organ system describes events in te
their relative frequency of reporting in the data base. Events of major
importance are also described in the Warnings and Precautions sectio

The following definitions of frequency are used: frequent adverse eve
defined as those occurring in at least 1/100 patients; infrequent adverse
are those occurring in 1/100 to 1/1,000 patients; rare events are those
ring in fewer than 1/1,000 patients.

Body as a Whole —*Frequent:* headache, asthenia, accidental injury, a
inal pain, chest pain, back pain, flu syndrome, neck pain, fever; *Infre*
facial edema, chills, enlarged abdomen, malaise, neoplasm, hernia,
pain, sepsis, cellulitis, moniliasis, abscess, jaw pain, hypothermia; *Rare*

Letters to the Editor

Letters to the editor should be submitted as an original and two duplicates. They should be typewritten double-spaced on plain bond paper; they will be subject to editing. If they are prepared on a word processor, do not justify the right margin. A copyright transmittal letter signed by all authors must accompany this (see "Instructions for Authors").

Migraine With Vasospasm and Delayed Intracerebral Hemorrhage

To the Editor.—Cole and Aubé[1] suggested that, in severe migraine attacks, vasospasm may result in ischemic necrosis of intracranial vessel walls, leading to a subsequent vessel rupture responsible for delayed lobar intracerebral hemorrhage, when perfusion pressure is restored. They stated that, except migraine, "subarachnoid hemorrhage, cerebral trauma, central nervous system infection, drug abuse, toxemia, fibromuscular dysplasia, carotid artery dissection, and cerebral vasculitis have all been associated with the radiographic appearance of spasm of the cerebral arteries." Another possible cause for vasospasm is cerebral embolism. We recently described rupture of the arterial wall in two cases of cerebral embolism.[2] One patient suffered a frontal hematoma. As proposed by Villaret et al,[3] arterial spasm may have occurred at the time of cerebral embolism. The morphological expressions specific to cerebral vasospasm are unknown. Cole and Aubé[1] suggested rupture of the arterial wall, secondary to ischemic necrosis. We[2] have had the opportunity to demonstrate such a rupture at the level of an embolic occlusion, preventing any substantial narrowing of the arterial lumen. The resulting local and violent arterial spasm lead to rupture of the vessel wall. No ischemic necrosis was seen. Whatever the underlying mechanism, rupture of the arterial wall must be considered when intracerebral hemorrhage is associated with any potential cause of cerebral vasospasm.

Migraine and Intracerebral Hemorrhage

To the Editor.—Intracerebral hemorrhage in migrainous patients has only rarely been reported.[1-7] Cole and Aubé[8] recently described three women with lobar intracerebral hemorrhage either during or immediately following typical migraine attacks. The patients did not have evidence of underlying conditions predisposing to intracerebral hemorrhage. The authors suggested vasospasm with necrosis of the vessel wall followed by sudden reperfusion as the cause of rupture of ischemic vessels, resulting in hemorrhage. Clinically, they observed that a migraine attack associated with bleeding was similar to the patient's usual headaches, but somewhat more severe and prolonged. Furthermore, in two patients carotidynia was observed.

We previously described 11 migrainous patients with intracerebral hemorrhage associated with migraine attacks.[9] All of the patients were diagnosed by computed tomographic scan and studied by carotid angiography, cranial magnetic resonance imaging, or both. The mean age was 35.8 years (range, 19 to 48 years). Nine subjects were women, four had a family history of migraine. Six subjects suffered classic migraine and five common migraine. In 10 patients we found the following predisposing conditions for hemorrhage: hypertension in five, vascular malformations in four, and alcoholism in one. In a 31-year-old woman with common migraine, who suffered a right capsular hemorrhage, we failed to find any underlying condition predisposing to bleeding. In seven patients neurologic manifestations due to intracerebral bleeding occurred more than 10 hours after headache started. All the patients presented with a headache similar to the previous attacks, but strikingly more severe.

In conclusion, intracerebral hemorrhage associated with a migrainous headache attack is usually associated with preexisting vascular anomalies. According to Cole and Aubé,[8] in cases without underlying conditions for intracerebral bleeding, severe vasospasm causing vessel wall necrosis may be a reasonable explanation for vascular rupture and hemorrhage during reperfusion. Furthermore, vessels previously debilitated by some diseases, like hypertension or alcoholism, may be prone to rupture during vasomotor and ischemic events in migraine.

In Reply.—De Smet and Brucher point out that two cases of intracerebral hemorrhage, both diagnosed at postmortem examination, appear to have been the result of arterial rupture following embolic occlusion. They propose that such rupture may be the consequence of local violent vasospasm following embolic occlusion. While our list of potential causes of cerebral vasospasm was not meant to be exhaustive, we would emphasize that none of our patients had evidence of embolic arterial occlusion demonstrated by acute angiographic studies.

Vazquez-Cruz has called our attention to his report of 11 patients with migraine who suffered intracerebral hemorrhage. Nine of those patients had hypertension or identified vascular malformations, one was an alcoholic, and one had no predisposing cause. We are unaware of an association between alcoholism and intracerebral hemorrhage except in the setting of coagulopathy or direct trauma. None the less, none of our patients were alcoholics. Migraine is a common disorder, and it is likely that a significant number of patients who sustain intracerebral hemorrhage, from whatever cause, also suffer from migraine. The point of our report was to emphasize that, in a number of patients without other identifiable cause for intracerebral hemorrhage, migraine itself may be causative. We suspect that Dr Vazquez's last case may fit into this group.

Isopropyl Alcohol Intoxication

To the Editor.—On reading the article "Isopropyl Alcohol Intoxication" by Rich et al[1] in the March issue of the Archives, I was struck by the fact that in all three of the cases presented there was nothing neurologically unique about these alcoholic subjects. In case 1, the sluggish pupils, prominent horizontal nystagmus, and appendicular and gait ataxia associated with peripheral neuropathy suggests Wernicke's encephalopathy.[2] No mention is made of treatment with thiamine. In case 2, the patient had an alcohol-related seizure and subsequent delirium tremens. I am surprised that a computed tomographic scan of his brain was not performed, given his recent head trauma. In case 3, the coma is consistent with intoxication with isopropyl alcohol, which is well described.[3]

The conclusions about the presentation of isopropyl alcohol intoxication presenting in two distinct patterns (stupor in a known alcoholic or encephalopathy in alcoholic subjects who hide their addiction) is not warranted. The only unique clinical points about isopropyl alcohol are the reflections of its metabolic handling. Unlike ethanol, ethylene glycol, and methanol, isopropyl alcohol causes ketosis without a significant wide-gap metabolic acidosis.[3] The emergent care of patients who may have ingested isopropyl alcohol involves support of the airway and attention to ruling out methanol or ethylene glycol ingestion. Since all three cause a widened osmolar gap, specific levels of ethanol, methanol, and ethylene glycol are necessary in order to make a decision about treating with an ethanol drip. This is not indicated for isopropyl ingestion, but is indicated for methanol and ethylene glycol. Finally, attention to replacement of both thiamine and niacin in any alcoholic with neurologic findings is paramount because the clinical diagnosis of either Wernicke's encephalopathy or alcoholic pellagra is very difficult.[4,5] There is very little toxicity associated with replacement therapy.

5. Serdaru M, Hausser-Hauw C, Laplane D, et al. The clinical spectrum of alcoholic pellagra encephalopathy. *Brain.* 1988;111:829-842.

In Reply.—We agree with Dr Wrenn that identification of the specific offending alcohol is important in managing patients with acute intoxications. One purpose of our report was to alert readers to the laboratory findings in patients with acute isopropyl alcohol intoxication, a disorder that we believe is common, yet little appreciated. Unfortunately, many breathalyzer tests as well as a newly introduced "saliva alcohol dipstick" method[1] do not distinguish between alcohols. We agree with his comments about management of the acute intoxications, including generous administration of thiamine in these patients, many of whom also abuse ethanol and eat sparingly and poorly.

Among the intoxicant alcohols (ethanol, methanol, isopropyl alcohol, ethylene glycol) isopropyl alcohol and ethanol are the only ones that are repeatedly and deliberately ingested for prolonged periods. The chronic effects of isopropyl alcohol are thus important. We are pleased to know that Wrenn's neurological experience in emergency medicine is extensive enough that he can chide us on the neurological uniqueness of our case 1, the only patient with chronic isopropyl alcohol use. Wrenn thinks the patient's findings are not separable from Wernicke's encephalopathy. During the senior author's (L.R.C.) training at the Boston (Mass) City Hospital and since, he has seen well over 100 patients with Wernicke's encephalopathy and is very familiar with the findings. In Wernicke's encephalopathy, the signs develop rapidly and are not due to a direct effect of ethanol or any other toxic agent on the nervous system and do not respond quickly to abstinence. The ocular findings may respond within hours to days to thiamine, but the other signs resolve more slowly or not at all. Our patient had the gradual onset of a constellation of signs that indicated diffuse cerebral, pyramidal tract, and cerebellar dysfunction that disappeared within 4 days of stopping isopropyl alcohol ingestion. He had received thiamine at the Boston City Hospital 3 weeks before and had been eating very well at his sister's house since then. His neurologic signs indicated subacute isopropyl alcohol toxicity and not Wernicke's encephalopathy. No other examples of subacute or chronic isopropyl alcohol intoxication have been reported to our knowledge, but we are confident that readers will now be able to identify such patients now that they are alerted to their presence and the findings.

Seizures After Stroke

To the Editor.—The study of epilepsy in stroke by Kilpatrick et al[1] probably represents the largest study to date of a topic that has been largely neglected.

However, we found the quality of data obtained rather disappointing. For instance, surely the authors should have strived to obtain complete electroencephalographic documentation of these patients, both with and without seizures. Conclusions drawn from electroencephalograms in the seizure group only are incomplete without a comparison with the nonseizure group, and even in these, only 26 of 44 patients had had electroencephalograms.

Similarly, in the 310 patients with cortical infarcts who were evaluated, 118 (38%) had "inadequate investigations." This is a surprisingly large number for a prospective study. Surely this huge unknown group invalidates any conclusions? Also, the authors seem to have lost 60 patients (the difference in totals between Tables 1 and 2).

Four of the 44 patients within the seizure group had previous epilepsy, but we could not find how many in the nonseizure group (956 patients) had previous seizures. Surely this is a relevant and critical omission?

In conclusion, we are disappointed by the degree of incompleteness of data collection, considering this was a prospective study. This criticism applies particularly to the nonseizure group, which should have acted as a large control group for comparison. The percentages of patients receiving the various investigations is not stated. The number that received computed tomographic scans (90%) is particularly disappointing. Clearly there are logistical problems in a large study of this kind, but if the quality of data collection falls below a certain level (only 62% were adequately investigated and age and sex ratios are not included), conclusions may give an unjustified sense of accuracy.

1. Kilpatrick CJ, Davis SM, Tress BM, Rossiter SC, Hopper JL, Vandendreisen ML. Epileptic seizures in acute stroke. *Arch Neurol.* 1990;47:157-160.

In Reply.—In reply to the letter from Zhu and Norris, we wish to make the following comments.

While we would accept that our large, prospective, clinical study has some limitations, we believe the data collected justify the conclusions made.

This study did not aim to assess the value of the electroencephalogram in predicting the risk of developing seizures in acute stroke. Clearly, electroencephalograms were not obtained from all patients, and we drew no conclusions from the electroencephalographic data collected.

The sex ratio of patients with seizures was the same as those without seizures (55% male, 45% female), and there was no significant difference in the mean age of patients with seizures (62 ± 10 years) and those without seizures (66 ± 15 years).

Table 2 does not list the pathogenesis of all cortical infarcts but only those pathogeneses associated with seizures, hence the difference between the total number of patients with carotid territory cortical infarcts in Table 1 and Table 2.

In this study, 118 (32%) of 370 cortical infarcts had unknown pathogenesis due to inadequate investigation. These patients had severe neurological deficits and no clear clinical signs of either a cardioembolic source or large-vessel atherosclerosis. It has been the practice in our institution not to routinely investigate the carotid circulation in those patients with clinical evidence of extensive infarction where carotid endarterectomy would not be contemplated. Overall, 40% of patients with cortical infarction were investigated with either digital subtraction angiography or carotid duplex scanning. As stated in the text, we were well aware of the large number of patients in whom the pathogenesis was unknown, often due to therapeutically appropriate but diagnostically inadequate investigation. We were, therefore, very cautious in making conclusions regarding the pathogenesis of cortical infarcts and the development of seizures.

Although we agree that ideally all patients with stroke or transient ischemic attacks should have a computed tomographic scan, in this study all patients with seizures had a computed tomographic scan and the overall computed tomographic scan rate of 90% is comparable with other stroke registries.[1]

We agree that it would be of interest to know the number of patients in the nonseizure group who had a history of epilepsy; however, this study did not aim to assess the association between cerebrovascular disease and a history of epileptic seizures. The history of epilepsy in four of the 44 patients with seizures complicating stroke was included as a possible precipitating factor.

As stated by Drs Zhu and Norris, the subject of epileptic seizures and acute stroke has received relatively little attention in the literature. Further studies to confirm our findings and, in particular, to assess the risk of recurrent seizures in these patients with acute seizures are needed.

Is Radiosurgery All That It Appears to Be?

To the Editor.—We were rather shocked by the publication entitled "Stereotactic Gamma Knife Radiosurgery, Initial North American Experience in 207 Patients," by Lunsford and coworkers,[1] that appeared in the February 1990 issue of the Archives. The attractiveness of a painless therapy such as radiation appears to have beguiled the authors and editors into overlooking the substantiation of assumptions that were expressed in the abstract of this article.

At the Neurological Institute of New York, we have had extensive experience in all modes of treatment for arteriovenous malformations (AVMs), including microsurgery, embolization, and radiosurgery (linear accelerator). Over the past 10 years, we have evaluated over 600 patients and have operated on, embolized, and recently carried out radiosurgery on these patients. This experience has allowed us to evaluate the characteristics of many AVMs in patients who have come for an opinion on therapy, proposed or already performed.

Thus far, less than three of our patients per year have had AVMs deemed appropriate for radiosurgery on the basis of size and inoperability. Given our annual experience, it is of concern to us that Lunsford and coworkers, using their criteria of "inoperability, failed surgery, and desire of the patient," have treated approximately 85 patients with AVMs per year by radiotherapy. Included in their group must be a large number where the lesions exceeded the size criteria for expected success, or small and superficial lesions that an experienced surgeon could remove with minimal morbidity.

While all of us are striving to advance the treatment of AVM, the implication that radiosurgery is a safer and more effective therapy fails to be confirmed in this article. The data provided in the body of their article does not substantiate their statement in the abstract that radiosurgery is a therapeutically effective alternative to microsurgical removal of AVMs. Of their 113 patients with AVMs, 12 patients were followed up for 1 year. Only five of these patients showed the AVM to be angiographically obliterated, and yet their technique is touted as a viable alternative to microsurgery. Furthermore, our experience with surgery and embolization indicates that it is fallacious to assume that the "angiographic residual" after embolization accurately reflects the true boundary of the AVM.

Lastly, it is yet to be shown that an effective level of radiotherapy applied to an AVM will prove safe in the long term.

---

1. Lunsford LD, Flickinger J, Coffey RJ. Stereotactic gamma knife radiosurgery: initial North American experience in 207 patients. *Arch Neurol.* 1990;47:169-175.

In Reply.—The response to our publication that appeared in the February 1990 issue of the Archives is most interesting. The goal of surgical treatment of vascular malformations, whether by microsurgery or by radiosurgery, is the same: total obliteration of an arteriovenous malformation (AVM) with preservation of neurological function, ultimately leading to the elimination of the risk of bleeding. The relative recent availability of radiosurgical techniques in the United States has led to a widespread evaluation of single-fraction, highly focused photon irradiation of AVM that is deemed unsuitable for conventional microsurgical removal. The great risk in radiosurgery (as opposed to microsurgery) is that during the treatment the patient feels nothing and the doctor sees nothing. No physician team involved in radiosurgery should be beguiled by this feature, as the benefits of radiosurgery and the risks do not accrue until later.

Dr Stein indicates that in the past 10 years, he has evaluated and subsequently "operated on, embolized, and recently carried out radiosurgery" on 600 patients with AVM. This is a treatment rate of approximately five patients per month. We treated 113 patients in a 16-month period, ie, seven per month. Between two major tertiary academic medical centers (the University of Pittsburgh [Pa] and Columbia University [New York, NY]) this difference is probably not statistically significant. Because of the known size limitations for radiosurgery and the availability of competent neurosurgeons, we found that the patient population referred to us was already preselected by the referring physicians for small size and/or high risk for surgery. It is further important to point out that, in order to treat 113 patients in the interval reported in our article, more than 400 patients with AVMs were carefully screened by evaluating both clinical indications and radiographic studies. We selected patients for radiosurgery if the AVM was of suitable size for radiosurgery, and microsurgery was felt to be too risky, or was refused by the patient. The opening of the first North American gamma unit at the University of Pittsburgh undoubtedly tapped a storehouse of diagnosed, but previously untreated, AVM. Our referrals have come from neurologists, internists, patients themselves, and more than 50 different neurosurgeons.

All patients are discussed preoperatively at a Combined Arteriovenous Malformation Conference that is held twice a month at the University of Pittsburgh. This conference is attended by neurological surgeons skilled in both microsurgery and radiosurgery, radiation oncologists, radiation physicists, and radiologists. All patients are evaluated as to what modalities will best suit the particular patient (no treatment, embolization, microsurgery, or radiosurgery alone or in combination).

We expect that as Stein and coworkers' experience with radiosurgery increases, they will find more AVMs suitable for radiosurgery. It is also interesting that Stein and coworkers express, on the one hand, concern referable to the field of radiosurgery while, on the other hand, adopt a linear accelerator technique, for which the least amount of long-term data exists as to either safety or efficacy. This is in contrast not only to our North American experience using stereotactic radiosurgery with the gamma unit, but also to the more than 20 years of experience accumulated at sites in Europe and elsewhere. We completely agree that radiosurgery must be thoroughly, scientifically, and rigorously evaluated in order to determine its role vs the alternatives of doing nothing or embolization or microsurgery. Fortunately, in the scientific community of the United States, this is proceeding rapidly. For example, an International Symposium on Radiosurgery was offered last year in Charlottesville, Va, another symposium will be presented in June 1990 in Boston, Mass, and the University of Pittsburgh will host an International Radiosurgical Symposium in June 1991.

The purpose of our article in the Archives was to bring (to the attention of physicians not familiar with radiosurgery) its possible therapeutic potential for treatment of AVMs and brain tumors. Since August 1987, we have treated 239 patients with AVM (7.5 patients per month); our results parallel previous reports, eg, a total AVM obliteration rate of 72% (defined as complete disappearance by angiogram within 2 years). Perhaps Stein and coworkers have read more into our abstract than was printed: "the results were encouraging during the minimum follow-up period of 6 months" . . . "In addition, our initial experience further suggests that stereotactic radiosurgery using the gamma unit is a therapeutically effective and economically sound alternative to microneurosurgical removal of selected intracranial tumors and vascular malformations." Our data then and now support this concept.

The Pathogenesis of Dermatomyositis

Considerable progress has been made in the understanding of dermatomyositis. Banker and Victor[1] characterized childhood dermatomyositis as an angiopathy in 1966. Banker then identified distinctive capillary endothelial changes and postulated that these were an early and fundamental lesion in dermatomyositis.[2] Subsequently, Carpenter et al[3] showed endomysial capillary necrosis and significantly reduced capillary numbers relative to muscle fiber area, providing substantive support for muscle fiber atrophy being a sequel of chronic sublethal ischemia.

See also p 26.

In this issue of the ARCHIVES, Kissel et al[4] provide still more evidence for the primacy of blood-vessel damage as an early pathologic feature of dermatomyositis. The report by Kissel et al[5] followed up on an earlier study from the same group, which showed that membrane attack complex (MAC) was present on muscle biopsy in blood vessels of patients with dermatomyositis. The present study used quantitative histologic methods, combined with immunofluorescent studies of MAC to show that the presence of MAC in capillaries in certain regions of the muscle was coextensive with muscle fiber damage. Membrane attack complex deposition presumably damaged or occluded vessels. This deposition preceded the wide array of muscle fiber damage that can occur in dermatomyositis.[6] The observations by Kissel and coworkers also support studies that have suggested that inflammation follows, rather than precedes, muscle damage in dermatomyositis.[7,8]

Both the present and previous studies by Kissel's group are based on studies of the C5b-9 complement MAC. Membrane attack complex is the final pathway for both the primary complement cascade, as well as the alternative complement pathway.[9] When the complement cascade is activated, new antigenic sites (neoantigens) are presented and these neoantigens can be detected by immunofluorescent techniques applicable to routine frozen muscle biopsy sections. Membrane attack complex has been identified as important in connective tissue diseases such as systemic lupus erythematosus, and may well contribute, to some extent, to phagocytosis of muscle fibers in conditions not considered primarily inflammatory, such as Duchenne's dystrophy.[10]

The importance of humoral immunity as an early and initiating event in dermatomyositis was suggested by Whitaker and W.K. Engel, who found that IgG, IgM, and complement were deposited in the walls of the muscle capillaries of patients with dermatomyositis.[8] As in the studies by Kissel and coworkers, these changes appeared within vessels that did not have inflammation and appeared normal by light microscopy.[8]

Membrane attack complex is a critical mediator of humoral, immunologic lysis of cell membranes.[9] The studies by Kissel and coworkers corroborate studies published earlier this year by Emslie-Smith and A.G. Engel[11] in which MAC deposition was found in blood vessel walls in dermatomyositis. These authors, using a lectin marker for capillaries, also confirm the earlier findings of Carpenter et al[3] and Carry et al[12] of a reduced number of capillaries relative to muscle fiber area. Taken together, these recent investigations strongly support the thesis that humorally mediated damage to blood vessels initiates the angiopathy of dermatomyositis affecting both capillaries and larger blood vessels. Occlusion of larger blood vessels may lead to actual infarcts.[3]

If, as the studies by Kissel and coworkers suggest, MAC deposition initiates or perpetuates local blood vessel damage, the complement cascade could have been activated by antibody binding to blood vessels as has previously been reported in dermatomyositis.[8] The MAC-containing capillaries occur in clusters.[5,11] This distribution of MAC suggests that complement activation occurs as the result of a pathological process in a larger, more proximal vessel or that a local process in a region of capillaries results in local initiation of the complement cascade.[13] Alternatively, an abnormality in one of the proteins that regulate MAC could be present. The S protein[14] and the complement receptor protein, CR-1,[15] have been found to be abnormal in systemic lupus erythematosus, where MAC appears to be of pathogenic importance.[16] The frequent presence of tubuloreticular structures in endothelial cells may be relevant to MAC deposition.[6]

What inciting factor or process causes antibody deposition and activates the complement cascade? Presently, no definite answer exists. Viral infection is a possibility. It has been supported by a documented case of influenza B virus producing the histopathologic appearance of dermatomyositis.[17] There is also a recent report of picornovirus RNA in the muscle of patients with dermatomyositis, but the localization is to macrophages and not the microcirculation.[17]

The idiopathic inflammatory myopathies are now sufficiently well understood to justify their classification into three major subgroups as follows: dermatomyositis, inclusion body myositis, and polymyositis.[19] There is hope that the pathogenesis and optimal therapy of each of the trio will be completely defined in the foreseeable future. Distinctive clinical features and characteristic muscle pathology now define these disorders. Dermatomyositis usually has a virtually pathognomonic skin rash and equally distinctive changes on nail-fold capillary microscopy.[20] Although the pattern of weakness is not specific, the muscle pathology of dermatomyositis is pathognomonic, although there can be marked regional variability of the severity of the changes.[19]

First recognized in 1971,[21] inclusion body myositis can often be recognized clinically by the relatively frequent distinctive distal weakness involving anterior tibial and wrist flexor muscles and the accompanying severe quadriceps weakness. Later, moderate proximal weakness develops. The distinctive light microscopic features of rimmed vacuoles that contain 15- to 18-nm tubulofilamentous masses define inclusion body myositis.

Idiopathic polymyositis lacks the pathognomonic pathological features that characterize either dermatomyositis or inclusion body myositis, but the presence of partial invasion of nonnecrotic muscle cells by cytotoxic lymphocytes[23] and the presence of conspicuous expression of class I major histocompatibility complex products on the surface of practically all muscle fibers are quite characteristic features.[24] Thus, polymyositis, in contrast to dermatomyositis, appears to be a cell-mediated disease. The clinical and pathological features of idiopathic polymyositis may be indistinguishable from other more specific forms of inflammatory myopathies, such as those associated with human immunodeficiency virus infection, human T-cell lymphotropic virus 1 infection, toxoplasmosis, or Lyme disease.

A number of major questions remain to be clarified with regard to the pathogenesis of dermatomyositis. Of course, the most pressing question is the primary etiology, but other issues are also important. Why are only skin and muscle (and rarely lung and intestines) involved? Is there any role for cell-mediated immunity? What host factors are important in the response to an inciting agent? The importance of this latter question is emphasized by the occurrence of the B8, DR3 histocompatibility antigens with increased frequency in patients with dermatomyositis, by the occurrence of dermatomyositis in identical twins, and by the evidence of specific anti-histidyl antibodies such as JO-1.[25] These antibodies are implicated in individual variations in the course of the illness; JO-1 antibodies are seen in only 20% of all patients with dermatomyositis, but are present in the majority of patients with interstitial inflammatory lung disease complicating dermatomyositis.[25,26]

A major goal of studies elucidating the pathogenesis of the inflammatory myopathies is to suggest new and more effective treatment strategies for dermatomyositis, inclusion body myositis, and polymyositis. Corticosteroids and immunosuppressants are the mainstay of treatment and are effective in virtually all cases of childhood, and many cases of adult, dermatomyositis.[27] Corticosteroids, often considered to have a greater effect on cellular rather than humoral immunity, are more effective in dermatomyositis or polymyositis despite evidence suggesting that humoral mechanisms are more important in dermatomyositis, while cellular mechanisms are implicated in polymyositis and inclusion body myositis.[19,28]

Intravascular deposits of circulating complexes may mediate vascular damage. Immunotherapy with monoclonal antibody can produce clinical remission in other vasculitic disorders.[27] Knowing that vascular damage is an early feature in dermatomyositis may pave the way for better treatment.

Caring for the Uninsured and Underinsured

There is a consensus among nearly all neurologists, as well as other groups of physicians and the general public, that a nation with the resources of the United States should make basic health care (including neurologic care) available to all citizens. At present, there are approximately 31 to 37 million Americans uninsured, including 16% of children under the age of 15 years, even though annual health care expenditures now exceed $600 billion (or 11% of the gross national product).[1] As the burden of paying for the excellence and excesses of our health system increases, the system's dropouts are mainly poor people and inner city hospitals. For example, patient encounters with physicians are 15% greater for white than for black citizens, even though twice as many blacks perceive their own health as fair or poor.[2]

In the spring of 1991, the *Journal of the American Medical Association* and the nine specialty journals of the American Medical Association will devote a portion of a special theme issue to "Caring for the Uninsured and Underinsured".[3] Since the *Journal of the American Medical Association* itself will address the financial aspects of care, the ARCHIVES is especially interested in contributions that reflect the authors' views concerning existing barriers to the care provided by neurologists, and what can be done about it. Many neurologists have expressed such views informally, and many professional organizations have discussed these vital issues. The American Medical Association is now providing an opportunity for groups and individuals to speak for the record. The ARCHIVES will submit contributions for peer review for possible publication in the "Practice of Neurology" section.

The astonishing advances in the diagnosis and treatment of many neurologic disorders during the past 30 years create a social imperative for neurologists and other physicians to be able to serve all people, to help devise ways to improve the health of our nation's downtrodden, to work toward equity for all groups in society, and to do everything possible to eliminate the morbidity and suffering of neglected neurologic disorders—yet without a wasteful "shotgun" approach to care that society can no longer afford. Clearly, past successes can create future failures, because so much more can now be done. The national community of neurologists must not let this happen.

The Relationship of Complement-Mediated Microvasculopathy to the Histologic Features and Clinical Duration of Disease in Dermatomyositis

John T. Kissel, MD; Richard K. Halterman; Kottil W. Rammohan, MD; Jerry R. Mendell, MD

• Accumulating evidence indicates that a complement-mediated microvasculopathy may play a pathogenic role in dermatomyositis. In a previous study, we demonstrated neoantigens of the C5b-9 complement membrane attack complex in the muscle microvasculature of childhood and adult cases of dermatomyositis. To further characterize the relationship between the vascular complement deposits and histologic changes, quantitative histopathologic analyses were performed on 39 dermatomyositis biopsy specimens (26 adult, 13 children). There was a significant correlation between the percentage of fascicles with fibers having focal myofibrillar loss, a change seen early in the evolution of ischemic muscle fiber damage, and the percentage of fascicles having capillary deposits of membrane attack complex. Conversely, in biopsy specimens with a higher percentage of fascicles with perifascicular atrophy, membrane attack complex deposits were significantly less common. A fascicle-by-fascicle analysis supported these observations. Patients whose biopsy specimens were negative for microvascular membrane attack complex had clinical weakness for a significantly longer time than those patients with vascular complement deposits. These data support the hypothesis that the complement-mediated vasculopathy is a primary immunopathogenic event in the evolution of muscle lesions in dermatomyositis.

(*Arch Neurol.* 1991;48:26-30)

A large number of studies has indicated that different immunopathogenic mechanisms distinguish childhood and adult dermatomyositis from the other idiopathic inflammatory myopathies.[1-11] Most evidence suggests that polymyositis and inclusion body myositis result primarily from direct cellular-mediated cytotoxic mechanisms,[1-5] while the muscle damage in dermatomyositis results from a complement-mediated microvasculopathy.[6-11] In a previous study, we demonstrated the presence of complement C5b-9 membrane attack complex in the intramuscular microvasculature of a significant proportion of dermatomyositis biopsy specimens.[11] These microvascular deposits of membrane attack complex appeared to be most prominent in zones of muscle with features of recent ischemic damage, including muscle fibers with punched-out or rarefied areas of myofibrils, pale-staining necrotic fibers with loss of the intermyofibrillar network, and wedge-shaped regions of contiguous muscle fiber necrosis characteristic of infarction.[3,9,12-15] In other areas of the biopsy specimens, particularly those with prominent perifascicular atrophy, a pathognomonic change of dermatomyositis, microvascular deposits of C5b-9 were scanty. Observations by other investigators demonstrating a loss of capillaries in the perifascicular area[3,7,9] suggested that complement-induced lysis might account for the decreased numbers of capillaries. Collectively, these observations led to the hypothesis that the earliest pathologic event in dermatomyositis is complement activation in the microvasculature followed by ischemic muscle fiber damage, leaving behind residual changes, including perifascicular atrophy and capillary loss.

See also p 21.

The study presented here was designed to test this hypothesis. Detailed quantitative histopathologic analyses were performed on muscle biopsy specimens from 39 patients with dermatomyositis to determine if the vascular C5b-9 deposits were related to the histologic changes observed in dermatomyositis of adults and children. In addition, membrane attack complex deposition in the microvasculature was compared with the duration of clinical disease for each patient.

METHODS

Biopsy Material

Limb muscle biopsy specimens obtained for diagnostic purposes from 39 consecutive cases of dermatomyositis (26 adults, 13 children) were studied. The biopsy specimens were stored at −70°C. Cases fulfilled the criteria of Bohan and Peter[16] for "definite" dermatomyositis, and patients with features of other connective tissue disorders ("overlap" syndromes) were excluded. All patients underwent biopsy prior to institution of immunosuppressive therapy. The biopsy specimens were stained with a battery of histochemical stains, as previously described.[17]

Quantitative Histopathology

Serial 4- to 6-μm cross-sections from each case were stained with modified trichrome and hematoxylin-eosin, and for membrane attack complex. Immunostaining for membrane attack complex employed a rabbit polyclonal antiserum to neoantigens of human C5b-9 and a standard indirect immunoperoxidase method previously reported.[11] For each case, the pattern of fascicles was outlined with the aid of a drawing tube attached to a microscope (Leitz Laborlux) (Fig 1). The fascicles in this outline were then numbered and sequentially examined for the following histologic changes:

1. Fibers with focal myofibrillar loss had "punched-out" or focal pale-staining areas that were usually central or paracentral in location. These fibers did not immunostain for membrane attack complex.
2. Necrotic fibers were pale staining on modified trichrome stain with positive immunostaining for neoantigens of membrane attack complex.[11,18]
3. Regenerating fibers were small with large, pale nuclei, and a basophilic appearance on hematoxylin-eosin staining.
4. Perivascular inflammation consisted of at least 10 mononuclear cells surrounding vessels greater than 30 μm in diameter in the perimysial or epimysial connective tissue.
5. Endomysial inflammation consisted of at least five inflammatory cells in the endomysium surrounding or focally invading muscle fibers.
6. Perifascicular atrophy was defined as a row of contiguous small fibers on at least two sides of the outermost layer of the fascicle adjacent to the perimysium. These fibers often, but not invariably, appeared to be regenerating according to the criteria outlined above.
7. Increased endomysial connective tissue was considered present in an individual fascicle if muscle fibers were consistently separated by at least 5 μm of connective tissue. This figure was chosen after review of the endomysial thickness surrounding 2000 individual normal muscle fibers.
8. Microvascular deposits of membrane attack complex consisted of immunoreactivity confined to the walls of endomysial capillaries.[11]

All histologic determinations were made by two investigators without knowledge of clinical information. Hematoxylin-eosin and trichrome stains were examined and quantitated independently of observations

on membrane attack complex immunostaining.

Clinical Data

Sufficient clinical information was available on 36 of 39 patients (23 adults, 13 children) to determine the duration of muscle weakness, pain, and fatigue at the time of biopsy.

Statistical Methods

Because the data were not normally distributed, nonparametric statistical methods were employed.[19] Data analyses were performed for all cases together (both childhood and adult), and independently for the adult and childhood groups to explore the possibility that adult and childhood cases behaved differently.

Quantitative Histopathology.—The histologic data were analyzed in two ways to determine if there was a correlation between vascular membrane attack complex deposition and any of the histologic variables examined. In the first analysis, the number of fascicles with each histologic change (eg, perifascicular atrophy, perivascular inflammation) was expressed as a percentage of the total number of fascicles examined for each patient group. These values were then compared with the percentage of all fascicles in each group with capillary membrane attack complex deposits using Kendall's tau correlation.[19]

In the second analysis, the numbers of fascicles with each histologic change *and* capillary membrane attack complex deposits were expressed as a percentage of all fascicles with that particular change (eg, fascicles with perifascicular atrophy and membrane attack complex deposits/total fascicles with perifascicular atrophy × 100%). Standard errors were calculated for each histologic variable and 95% confidence intervals were determined. A significant difference between the percentages for each variable at the $P < .05$ level was confirmed if the confidence intervals did not overlap.[19,20]

Clinical Duration Data.—The duration of clinical disease for each patient was expressed in weeks. The two-sample Wilcoxon rank sum test was then used to compare the durations between patients with and without microvascular membrane attack complex on biopsy for the three patient groups.[19,20]

RESULTS

Histologic Data

An average of eight fascicles was studied for each biopsy specimen (mean 7.8 ± 2.5; range, 4 to 15). Table 1 gives the total number of fascicles and the number and percentage of fascicles with each histologic change for the patient groups. Ten of 13 children and 11 of 26 adults had microvascular deposits of membrane attack complex in at least one fascicle of the biopsy specimen. As shown in Table 2, there was a significant correlation for all the cases between the percentage of fascicles having fibers with areas of focal myofibrillar loss and the percentage of fascicles having capillary deposits of membrane attack complex (correlation coefficient .569, $P = .00001$). This comparison was also significant for adult and childhood cases that were analyzed separately. In biopsy specimens with a higher percentage of fascicles demonstrating perifascicular atrophy, capillary deposits of membrane attack complex were significantly less frequent (correlation coefficient −.492, $P = .0002$). When the groups were analyzed separately, this inverse correlation was definitely significant for the adult cases ($P = .003$), but only approached significance for the childhood cases ($P = .056$). The difference in the childhood and adult cases reflects the higher frequency of deposits of membrane attack complex (10 of 13) in the younger patients, particularly at sites independent of areas of perifascicular atrophy. This point is illustrated in the fascicle-by-fascicle analysis (see below) that demonstrated that deposits of membrane attack complex were rare in fascicles with well-developed perifascicular atrophy in the childhood cases.

There was also a significant positive correlation between necrotic fibers in fascicles and the presence of microvascular membrane attack complex for

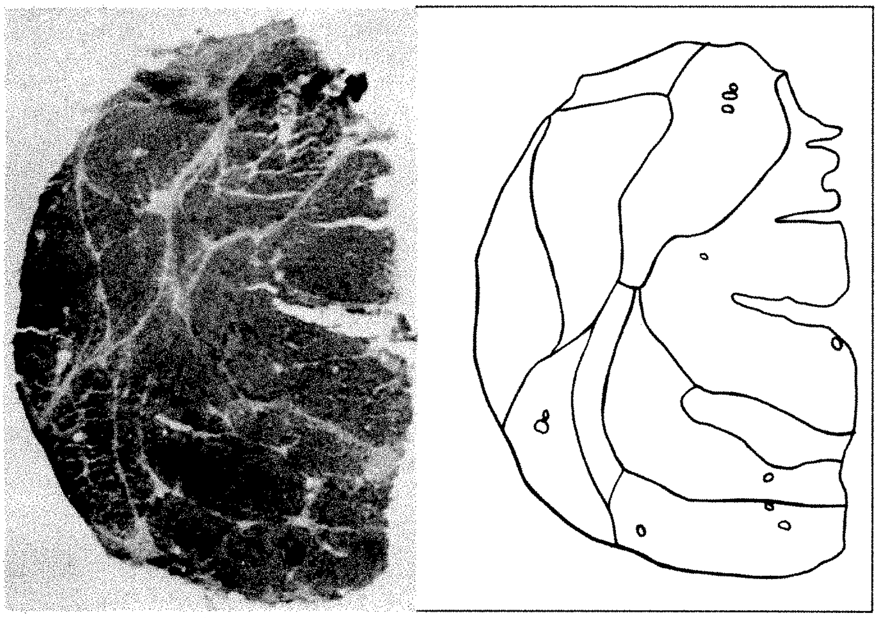

Fig 1.—Representative low-power view of a typical trichrome-stained adult dermatomyositis biopsy specimen (left) and the drawing tube representation of the fascicle pattern (right) used for the quantitative histopathology studies (×20).

the adult population and for all patients analyzed together (Table 2). None of the other histologic variables were related to complement deposition except for increased connective tissue, which showed an inverse relationship ($P = .011$) in the childhood cases.

Data specifically correlating capillary deposits of membrane attack complex and regional histologic changes are presented in Fig 2. Fascicles with fibers showing focal myofibrillar loss (Figs 3 and 4) were significantly more likely to have microvascular complement deposits than were fascicles with perifascicular atrophy (Fig 5) or perivascular inflammation. This observation was also valid for both childhood and adult cases that were analyzed separately. The degree of capillary and myofiber involvement differed significantly between fascicles. In some areas, well-defined circumferential capillary immunostaining was seen, often in association with only a few fibers with focal myofibrillar loss (Fig 3). In other fascicles with more advanced involvement, the capillary immunostaining assumed a more punctate appearance due to underlying capillary necrosis. In these fascicles, multiple fibers with focal myofibrillar loss were usually encountered (Fig 4).

Duration Data

The mean duration of disease and P values for the patient groups are presented in Table 3. As shown, patients whose biopsy specimens were negative for capillary membrane attack complex had had clinical disease significantly longer ($P = .0006$) than those patients with membrane attack complex in the microvasculature. This was particularly true for the adult patients who were considered separately. In the childhood cases, the duration of disease in relation to membrane attack complex deposits fell just below statistical significance ($P = .06$). This might be accounted for by an earlier presentation of the childhood cases or a greater likelihood of membrane attack complex deposits throughout the duration of the illness, representing more homogeneity in the pathogenesis of childhood cases compared with adult cases.

COMMENT

We hypothesized that, in dermatomyositis, complement deposition in the microvasculature is the earliest immunopathologic event that leads to capillary damage and muscle ischemia.[11] To test this hypothesis, muscle fiber histologic changes were analyzed in relation to deposits of membrane attack complex in the endomysial capillaries. Although microvasculature complement deposits are frequently seen in larger vessels in the perimysial connective tissue in both childhood and adult cases,[11] these vessels may be supplying blood to regions of muscle out of the plane of section, and, therefore, were not analyzed in this study. An additional methodological consideration is that for this study the histo-

Table 2.—Comparison of Fascicle Histologic Changes With Presence of Vascular Deposits of Membrane Attack Complex*

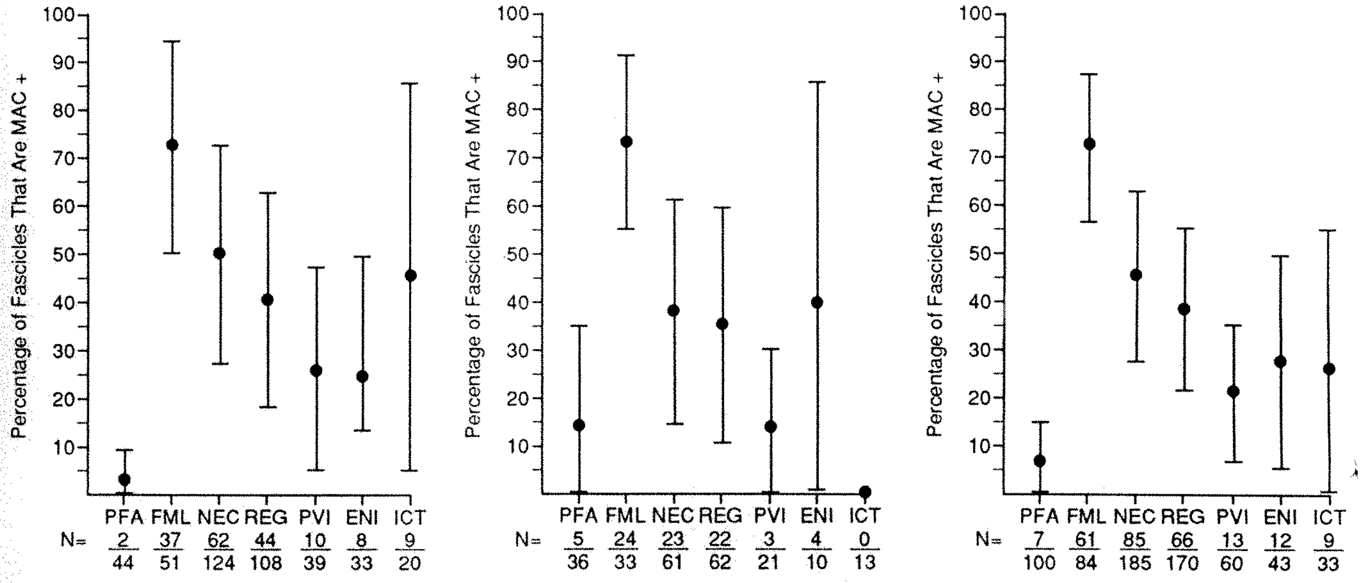
*For each comparison, the total number of fascicles in each patient group with a given histologic change was expressed as a percentage of all fascicles examined in that group. This was then compared with the percentage of fascicles with capillary membrane attack complex in each group. The numbers represent Kendall's tau correlation coefficient and corresponding *P* value for each comparison. Abbreviations are the same as those used in Table 1. NS indicates not significant.

Fig 2.—Comparison of the percentages of fascicles with positive vascular membrane attack complex immunostaining for the adult cases (left), childhood cases (center), and all cases analyzed together (right). The percentages on the ordinate represent the numbers of fascicles with each histologic change *and* capillary membrane attack complex deposits divided by the total number of fascicles with each histologic change. Bars represent 95% confidence intervals for each change. Lack of overlap between the confidence intervals indicates a significant difference between the proportions at the $P < .05$ level. See text for details. Abbreviations for histologic changes are the same as in Table 1.



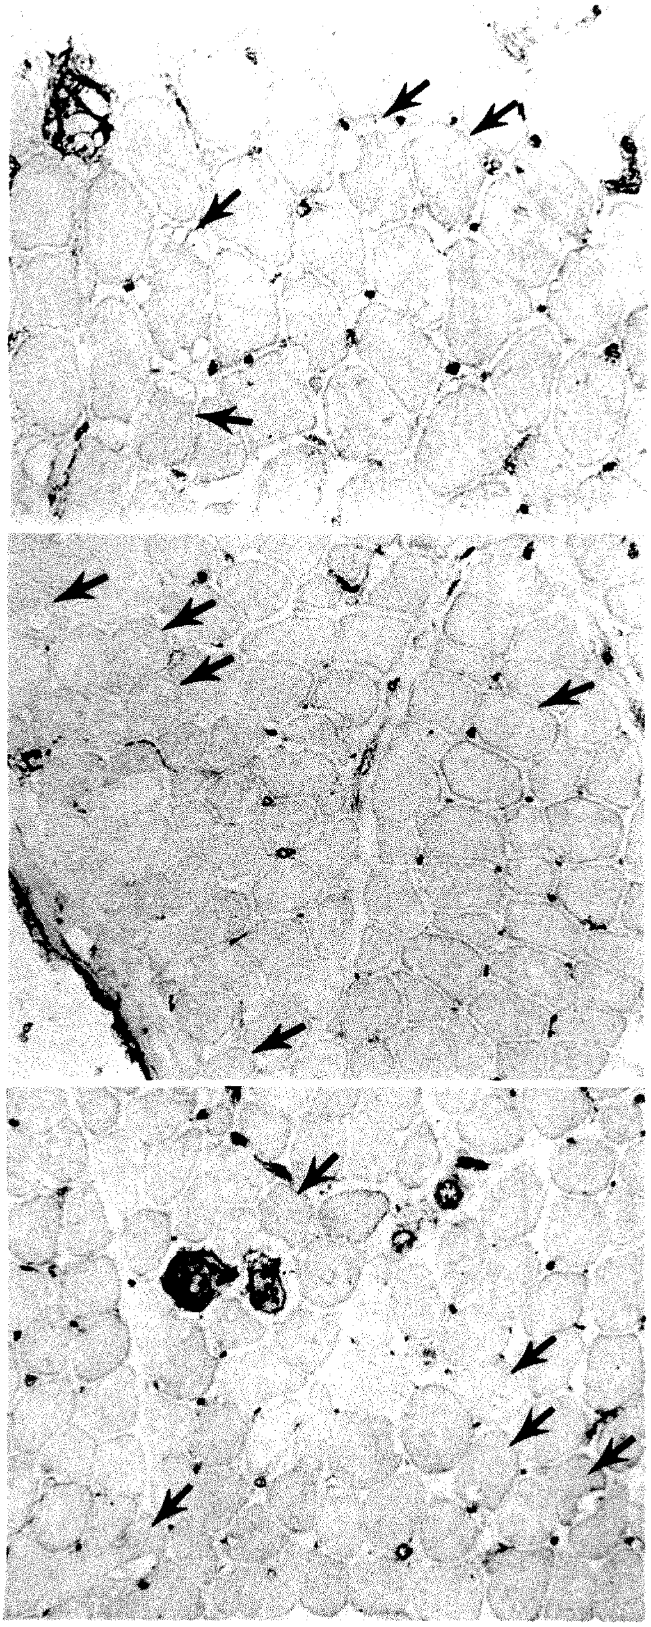


Fig 3.—Three representative areas from a childhood dermatomyositis biopsy specimen immunostained for membrane attack complex. Well-defined microvascular deposits are seen in fascicles with fibers having focal areas of myofibrillar loss (arrows). In top and bottom parts, necrotic muscle fibers also immunostain for membrane attack complex (top, ×260; center and bottom, ×200).

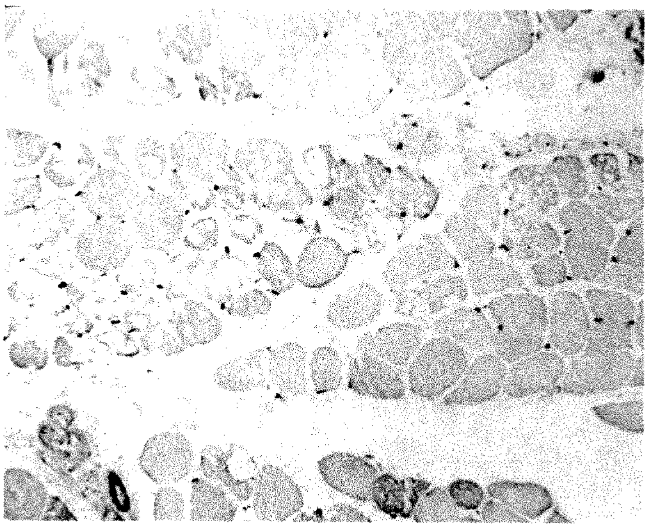

Fig 4.—Adult dermatomyositis biopsy specimen immunostained for complement membrane attack complex. In fascicles with multiple fibers having focal myofibrillar loss, intense punctate deposits are seen in the capillaries (×125).

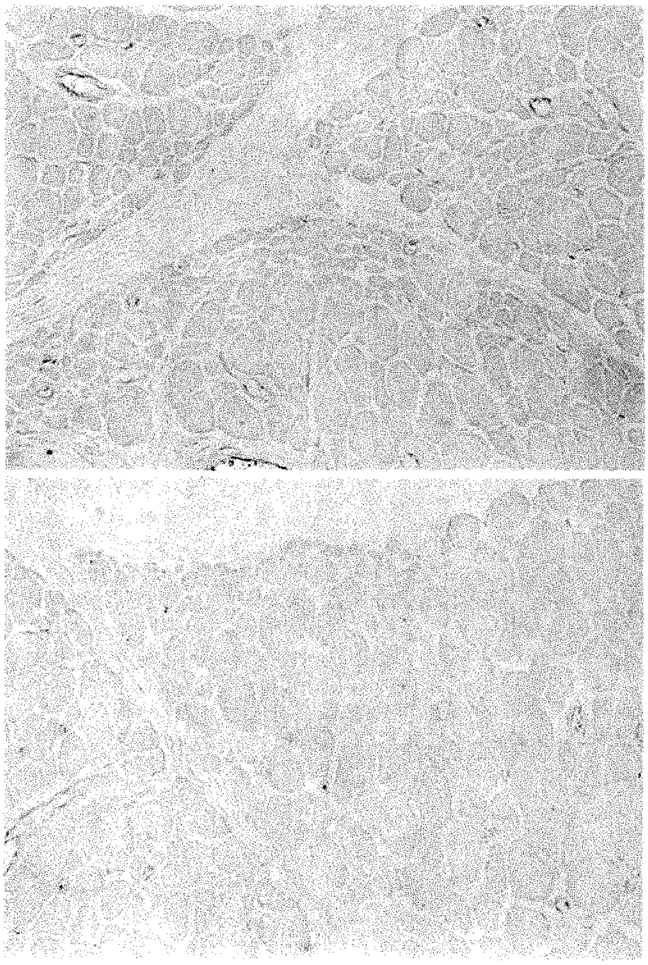

Fig 5.—Two areas (top and bottom) from an adult dermatomyositis biopsy specimen immunostained for membrane attack complex. The fascicles with prominent perifascicular atrophy have no microvascular deposits of membrane attack complex anywhere in the fascicle (×125).

logic changes in relation to complement deposition were analyzed separately for the biopsy specimen as a whole, as well as in relation to each individual fascicle. The latter analysis provided a satisfactory means to correlate capillary membrane attack complex deposits directly with contiguous histologic changes. This type of analysis is important in a disease such as dermatomyositis, where areas of a biopsy specimen may have markedly different histologic changes reflecting insults occurring at separate times in the evolution of the disease.

Our analysis revealed that membrane attack complex deposits in the microvasculature correlated significantly with the presence of fibers having focal areas of myofibrillar loss, a histologic change seen early in the evolution of ischemic muscle fiber damage.[9,12,13,15] This association was true in a fascicle-by-fascicle analysis, as well as for the entire specimen. Conversely, in fascicles with perifascicular atrophy, microvascular complement deposits were significantly less common, both in the perifascicular areas and in the more central regions of the fascicle. Our interpretation of these findings is that the association of microvascular deposits of membrane attack complex with early histologic changes of muscle fiber ischemia suggests a primary role for the complement system in the immunopathogenesis of the disease. Further support for this concept was provided in our study by comparing disease duration with the muscle biopsy findings. Microvascular complement deposits were significantly more common if the time interval between the onset of symptoms and muscle biopsy specimen examination was shorter. Independent histologic observations support this point of view. Recent studies by DeVisser et al[21] and Emslie-Smith and Engel[22] demonstrated that capillary deposits of membrane attack complex and reduced capillary density actually preceded muscle fiber damage in unaffected or minimally affected regions of muscle in adult patients with dermatomyositis.

Although our findings provide strong evidence that complement deposits occur early in the disease process, the results also raise the question of whether humoral immune mechanisms, specifically the complement system, represent a singular pathogenic mechanism in this disease. The findings of other investigators, especially in adult cases, support a possible transition or collaboration with other immune mechanisms. For example, in studies by Arahata and Engel,[4] the mononuclear cell subsets in dermatomyositis demonstrated a significant percentage of CD8$^+$/cytotoxic T cells and macrophages in addition to B cells and CD4$^+$/helper T cells, raising the possibility of cellular-mediated muscle fiber damage. These findings are of interest in light of studies demonstrating class I major histocompatibility complex gene products on muscle fibers from cases of dermatomyositis.[23,24] Such expression of class I antigens would be a necessary prerequisite for direct cytotoxic T-cell damage in dermatomyositis. These findings could be relevant in some cases of dermatomyositis where a clinically prolonged and more severe course is associated with marked perifascicular atrophy and absence of microvascular complement deposits on biopsy.

In summary, the clinical and histologic data presented here strongly support the concept that complement activation occurs as a primary immunopathogenic event in the evolution of muscle lesions in dermatomyositis. The variability in complement deposits in the muscle tissue of patients with dermatomyositis appears to depend on the area of muscle sampled,[11,21,22] as well as the time of muscle biopsy in relation to the evolution of the disease process. The data also suggest that complement may not be the only pathogenically significant immune mechanism throughout the entire course of the disease. Further understanding and definition of these immune mechanisms in dermatomyositis will be important in devising better treatment strategies for the future.

This study was supported by a grant from the Muscular Dystrophy Association, New York, NY.

Early Combination of Selegiline and Low-Dose Levodopa as Initial Symptomatic Therapy in Parkinson's Disease

Experience in 26 Patients Receiving Combined Therapy for 26 Months

T. S. Elizan, MD; D. A. Moros, MD; M. D. Yahr, MD

• Thirty-eight patients newly diagnosed as having Parkinson's disease (mean age, 57.3 years; mean Parkinson's disease duration, 2.7 years) in the earlier phase of the disease (mean Hoehn/Yahr stage, 2; mean motor scores, 11.4) were given selegiline (Deprenyl), 10 mg daily, and maintained on this drug alone until significant clinical worsening warranted the addition of low-dose levodopa (Sinemet, 25/100 three to four doses per day). Five of these patients were not yet receiving additional levodopa despite some worsening of motor scores. Of the 33 patients now taking combined therapy, seven have been followed up for 6 months or less. Twenty-four (92%) of the 26 patients taking combined therapy for a mean of 26 months (8.5 to 99 months) who have had Parkinson's disease for 6 years showed a dramatic improvement in their parkinsonism shortly after the addition of levodopa, with significant decreases in their rated motor scores, such improvement being maintained at their latest neurologic evaluation. Eighteen (75%) of these 24 patients responded to the combined selegiline/levodopa therapy with degrees of improvement equal to or greater than 50%, compared with their motor status at the start of combined therapy just before the addition of levodopa. This degree of "reversal" of parkinsonism on addition of levodopa (mean carbidopa/levodopa dose, 98/389 mg) was *not* observed in any of these same patients receiving selegiline alone for an average of 13.8 months. Four patients taking combined therapy developed mild, transient, abnormal involuntary movements, and end-of-dose pattern of response after more than 2 years of combined therapy (24.75 and 33.5 months, respectively). Our results on combined selegiline/levodopa therapy reemphasize the continuing dominant role of levodopa as the primary drug for the symptomatic treatment of Parkinson's disease. A possible synergistic role of selegiline with levodopa in the early cases is suggested by the sustained therapeutic effectiveness of even low doses of the latter for a period of 26 months, with a delay in the appearance of relatively minor side effects developing only after more than 2 years of combined therapy. At an average disease duration of 6 years, no patient has had a major functional disability. A concurrently studied control group of patients treated with low-dose levodopa alone, or one treated with a combination of low-dose levodopa and a dopamine agonist like bromocriptine or pergolide, may have clarified further the role of selegiline, but such control subjects were not available to us at this time. We suggest the early combination of a selective monoamine oxidase type B inhibitor like selegiline, and the original dopamine replacement drug, levodopa (as low-dose Sinemet), as initial symptomatic therapy in newly diagnosed cases of Parkinson's disease.

(*Arch Neurol.* 1991;48:31-34)

Selegiline (L-Deprenyl), an amphetamine-derived, potent, irreversible inhibitor of the enzyme monoamine oxidase type B, has been under investigation since 1975 as an agent that may arrest or slow the natural progression of Parkinson's disease (PD).[1] Although originally designed as an antidepressant, the drug's pharmacologic features[2,3] have led to its use as an adjunctive agent to levodopa, as recently reviewed.[4,5] Briefly, the current underlying rationale for its use is based on two kinds of observations: (1) monoamine oxidase inhibitors, including selegiline, prevent the biological (toxic) effect of 1-methyl-4-phenyl-1, 2, 3, 6-tetrahydropyridine (MPTP) on dopamine neurons in experimental animals[6-8]; (2) during catabolism of dopamine by monoamine oxidase, a potential cellular oxidant, hydrogen peroxide, is formed, and selegiline appears to suppress such an oxidative stress associated with increased dopamine turnover in animal models.[9,10] Increased dopamine turnover that inevitably occurs in PD may be viewed as a potential source of an oxidant stress. This protective role of selegiline in experimental systems would be most relevant if indeed idiopathic PD in man is caused by a toxin (endogenous or exogenous), for which no definitive evidence, as yet, exists.

We recently presented our clinical experience with selegiline on 22 de novo patients with early PD,[11] and as an adjunct to long-term conventional levodopa (Sinemet) therapy in 200 patients with advanced PD.[5] Selegiline by itself does not halt the clinical progression even in early PD,[11] but may apparently delay the onset of functional disability compared with the course of early, otherwise *untreated*, control subjects.[12,13] When given much later in the course of the disease as an adjunct to long-term levodopa therapy, selegiline mildly improved the parkinsonian state for a limited time in a selected group of patients experiencing an end-of-dose pattern of response to levodopa.[5]

In following the course of our de novo patients taking selegiline alone,[11] we were impressed with the observation that almost immediately (within weeks) after the addition of a starting minimal dose of levodopa, the worsening parkinsonism dramatically improved, such improvement being maintained. Additionally, we know from our extensive experience with levodopa since 1968, that an optimal levodopa dose is generally reached within the first year of treatment. This article focuses on our experience with the early combination of selegiline and low-dose levodopa as initial symptomatic therapy in early PD.

PATIENTS AND METHODS

Patients registered at the Mount Sinai Parkinson's Center (New York, NY) with newly diagnosed PD in its early phase, and who had not had previous selegiline or levodopa therapy, agreed to participate in this study, and signed informed consent forms approved by Mount Sinai's institutional review board on human studies. To date, 38 patients have chosen to be involved. All had a complete neurologic evaluation

just before entering the study, and their parkinsonian state was rated by two neurologists at regular intervals using Mount Sinai Center's functional staging of disease severity (stages I through V) and rated motor disability scores (25 items, rated 0 to 4). Twenty-one of these patients were in the original group of 22 de novo patients tried on selegiline alone, whose treatment results we recently presented.[11] These patients received selegiline, 5 mg twice a day, and no other therapeutic agents, until such time as their condition showed functionally significant progression, determined by more than 25% deterioration in their parkinsonian-rated examination and/or advancement to a more severe functional stage of the disease. At such time, the patient was offered the opportunity of having levodopa (Sinemet) added, which was usually begun at a minimum dosage (25/100, two to three doses per day) and titrated to achieve optimal antiparkinsonian effect. Nine other de novo patients were similarly treated with selegiline and given additional levodopa when worsening functional deficits when receiving selegiline alone warranted such addition. In an additional eight de novo patients treatment was started almost simultaneously with both selegiline and levodopa within days of one drug and the other, without waiting for any further change in the course of the disease while receiving one drug alone.

At the start of the trial, these 38 patients had a mean age of 57.3 years, mean PD duration of 2.7 years, mean Hoehn/Yahr stage of 2.0, and mean motor scores of 11.4. At their latest neurologic evaluation, five of these patients receiving selegiline alone for an average of 25.6 months, had not yet elected to take additional levodopa, despite some worsening of their motor scores. Seven patients have been given combined selegiline/levodopa therapy for 6 months or less. The remaining 26 patients who have been receiving combined therapy for more than 6 months (mean of 26 months) constitute the subject of this article.

RESULTS

Table 1 shows the demographics of this patient population. At the start of their combined selegiline/levodopa therapy, just before the addition of levodopa, these 26 patients had been receiving selegiline alone for an average of 13.8 months. At the time of their latest neurologic evaluation, 62% of these patients had been taking combined therapy for 8 to 24 months, and 38% for over 2 to 5 years (average duration of 26 months). At this time, they had had PD for an average of 6 years and were given an average Sinemet dose of 98 mg, carbidopa, and 389 mg of levodopa. The maintenance dose of selegiline, 10 mg a day, was unchanged from that previous to the addition of levodopa.

Table 2 shows the disease stage and parkinsonian motor scores of each of these 26 patients at the start of the combined selegiline/levodopa therapy, and at their latest neurologic evaluation. In the eight patients marked with asterisks treatment was begun almost simultaneously with both drugs. The most striking "reversal" of parkinsonism occurred in two of these patients (patients 19 and 25), with almost normal motor status after over 2½ years (32 months) of receiving combined therapy (on 93.75/375 mg Sinemet), who have had the disease for 7 and 4 years, respectively. Of the 24 patients that did improve by taking combined therapy, the average improvement was 65%. Two patients (patients 11 and 27) with unchanged stages and mildly worsening motor scores (27 vs 39.5 and 14 vs 17) at their latest evaluation 8.25 years and 3.3 years after start of their combined therapy, respectively, were on the 11th and sixth year of their disease, and have had a gradual worsening of scores before and after the start of combined therapy.

Table 3 summarizes the severity of parkinsonism in these 26 patients before any therapy was given; at the start of combined therapy (or just before addition of levodopa after a trial with selegiline alone for an average of 19.8 months in 18 of 26 patients); and, at the latest examination, over 6 months from start of combined ther-

Table 3.—Severity of Parkinsonism in Patients Receiving Early Combined Selegiline/Levodopa Therapy for Over 6 Months*

	Disease Stage		Motor Scores’	
	Total	Average	Total	Average
Before therapy	56	2.2	338	13
At start of combined therapy	58	2.2	460	18
At latest examination >6 mo from start of combined therapy	46	1.8	199	8

*N = 26 patients.

Table 4.—Improvement in Motor Scores of 24 Patients Receiving Combined Selegiline/Levodopa Therapy for Over 6 Months*

No. (%) of Patients	Degrees of Improvement, %
9 (37.5)	80-100
9 (37.5)	50-79
3 (12.5)	20-49
3 (12.5)	0-19

*Seventy-five percent of 24 patients responded on the combined selegiline/levodopa therapy with a degree of improvement equal to or greater than 50%.

Table 5.—Untoward Events Developing During Combined Selegiline/Levodopa Therapy

Event	No. of Patients	Comment
Death (cancer, lung; myocardial infarction)	1	Patient had been taking combined therapy for 8.75 months until death
"Bleeding" peptic ulcer	1	Patient had been taking combined therapy for 47.5 months when selegiline was stopped
End-of-dose deterioration	4	Event was first noted on the 40th, 36th, 34th, and 24th month of combined therapy, respectively
Abnormal involuntary movements	5	Event was first noted on the 36th, 34th, 18th, 16th, and 13th month of combined therapy, respectively

apy. There was a worsening of motor scores greater than 30% (36%) from initial evaluation to the start of combined therapy. A striking improvement of motor scores greater than 50% (57%) was noted at the latest examination over 6 months from start of combined therapy compared with status at the start of combination treatment. This "reversal" of deteriorating motor scores was evident even when comparison was made with the initial pretherapy scores (41% better than pretherapy scores).

Table 4 shows the degrees of improvement in motor scores of 24 of 26 patients who improved by taking combined therapy. Eighteen (75%) of the 24 patients responded with degrees of improvement equal to or greater than 50%. Seven of these patients also had a concurrent shift to at least one functional stage better than at the beginning of combined therapy (Table 2). These degrees of improvement or "reversal" of parkinsonism were *not* observed in any of these same patients receiving selegiline alone for over 1 year. All patients have remained totally functional with no major parkinsonian disability at an average disease duration of 6 years.

Table 5 shows the untoward events that developed during combined therapy. One patient (patient 16) died suddenly of myocardial infarction and a recently discovered lung cancer, 2 months after his latest neurologic evaluation at which time he showed improving motor scores (66% change) after almost 9 months of taking combined therapy. This 70-year-old man was taking selegiline alone for 2 years during which time he continued to deteriorate, almost doubling his motor scores. Reversal of scores occurred within 1 month after addition of levodopa. He returned to work 5 months later. Before he died he was still receiving a maintenance dose of 10 mg of selegiline and 100/400 mg of Sinemet. One patient (patient 12) had been taking selegiline alone for 7 months, and receiving combined selegiline/levodopa for another 47.5 months, when he had a bleeding peptic ulcer and he stopped the selegiline. Now he is only taking Sinemet 200/800 mg daily. Four patients (patients 11, 12, 24, and 27) first developed an end-of-dose "wearing off" pattern of response on the 40th, 36th, 24th, and 34th month, respectively, of combined therapy (mean, 2.8 years after addition of levodopa). Interestingly, the same four patients also first developed abnormal involuntary movements at the 16th, 36th, 13th, and 34th month, respectively, of combined therapy (mean, 2.0 years after addition of levodopa). Sinemet doses at those times were 100/400, 225/900, 125/500, and 75/750 mg daily, respectively (or a mean of 131 mg of carbidopa/637.5 mg of levodopa). The abnormal involuntary movements were focal, localized to small muscle groups of the hand, foot, or face, transitory (seconds), infrequently occurring, and were at no time disabling. One more patient (patient 13) developed one episode of mild, transient "curling up of left foot" at the 18th month after Sinemet was added at a dose of 75/300 mg. There have been no instances of mental confusion, disorientation, hallucinations, behavioral changes, or changes in higher cognitive functions ever occurring in any of these 26 patients during this combined drug trial, which has now lasted for a mean duration of 26 months or 2.2 years (range, 0.7 to 8.3 years; median, 4.5 years).

COMMENT

Our results on combined selegiline/levodopa therapy reemphasize the continuing dominant role of levodopa as the primary drug for symptomatic treatment of PD. It was the addition of initial small doses of levodopa to a deteriorating parkinsonism on selegiline alone for an average of 13.8 months that rapidly and dramatically "reversed" the clinical worsening in most of our patients. Seventy-five percent of the 24 patients who did improve responded with degrees of improvement in their motor scores by as much as, or better than 50%, with a concurrent shift of at least one functional stage in about a third. These results are similar to those of the earliest article by Yahr et al[14] in 1971 on levodopa and MK-486 (α-methyl-dopa hydrazine), where 89% of their 38 patients had better than 50% improvement on the then new combination of levodopa and a peripheral decarboxylase inhibitor. Yahr et al noted that such results obtained within the first weeks of combined treatment were similar to those they had found after 6 to 12 months of treatment with gradually increasingly large doses of levodopa alone. Just as Yahr et al were impressed with the "effective, rapid and efficient means of reversing the parkinsonian state" with levodopa/MK-486 in 1971, we were impressed anew with the relatively dramatic reversal of parkinsonism with low doses of levodopa-carbidopa when added to a previous regimen of selegiline alone. This was particularly impressive in two of eight patients in whom treatment with both drugs was started almost simultaneously, with rapid reversal to almost normal motor status, maintained after over 2½ years on combined therapy. The quality of the therapeutic response was not related to the age of onset, severity, or duration of PD at the start of selegiline/levodopa therapy. A possible synergistic role of selegiline with levodopa in these early cases of PD is suggested by the sustained therapeutic effectiveness of even low doses of the latter for an average of 26 months, with a delay in the appearance of relatively minor side-effects that developed only after over 2 years of combined therapy. At an average PD duration of 6 years (range, 3 to 11 years), no patient has had a major functional disability. While these patients have now been followed up for over 2 years, it remains too early to draw any definitive conclusions regarding the specific role of either drug in this combination. A concurrently studied, appropriately matched control group of low-dose levodopa alone or in combination with a dopamine agonist such as bromocriptine or pergolide was not available to us at this time. Three articles in the recent literature address the issue of bromocriptine compared with, or in early combination with, levodopa, and present some data that may be historically relevant for our study. Libman et al[15] assessed the short-term efficacy and tolerance of bromocriptine (Parlodel) and levodopa-carbidopa in a double-blind parallel group design multicenter study of 49 de novo patients followed up for 3 months. The majority of their patients (21 in the bromocriptine group and 17 in the levodopa-carbidopa group) were in stage II or III of their disease at the beginning of the study, comparable with our own study group. At the end of 3 months, 42% of the patients in the bromocriptine group and 32% in the levodopa-carbidopa group had improved in their parkinsonian status by at least one functional stage. The total mean neurologic assessment scores had improved by 62% in the bromocriptine group and by 55% in the levodopa-carbidopa group. Comparison between the groups did not show any significant difference for both neurologic and disability assessments. The mean daily dose for responders at the end of 3 months was 22.5 mg of bromocriptine and 250 mg of levodopa. The most significant side effect observed was transient nausea occurring in six of 24 patients receiving bromocriptine and in three of 25 patients receiving levodopa-carbidopa. Rinne[16,17] described his experience with the early combination of bromocriptine and levodopa in patients with PD. Compared with levodopa alone, treatment with bromocriptine alone for 3 years, and then for 5 years, resulted in fewer fluctuations in disability and peak-dose dyskinesias, but also less improvement in parkinsonian disability. After 3 years of combined bromocriptine/levodopa treatment of 28 patients,[16] the mean daily doses of bromocriptine (16.6 ± 1.9 mg) and levodopa (660 ± 35 mg) were significantly lower than in patients treated with either drug alone (bromocriptine, 28.0 ± 4.3 mg in 21 patients; levodopa, 798 ± 12 mg in 217 patients). Three years of combined treatment resulted in significant improvement of parkinsonian disability equal to that achieved with levodopa alone (39% ± 3% vs 37.0% ± 1%), and significantly better than with bromocriptine alone (15% ± 3%). On a 3-year follow-up of patients treated with levodopa alone, there were fluctuations in motor disability in 51 (24%) of 217 patients; there were significantly fewer ($P < .05$) fluctuations in patients taking combined therapy. At 5 years of combined bromocriptine/levodopa therapy in 25 patients,[17] improvement of parkinsonism was equal to that observed in 196 patients receiving levodopa alone (23%). Rinne[17] concluded that as primary treatment, bromocriptine alone is not a useful antiparkinsonian agent, but that the early combination of low-dose bromocriptine and levodopa-carbidopa can result in a therapeutic response equal to that of levodopa alone, but with few end-of-dose fluctuations and peak-dose dyskinesias.

Our own initial results with the early combination of selegiline/levodopa compare favorably with the above historic data in the literature. We can only suggest that the early combination of a selective monoamine oxidase type B inhibitor, like selegiline, with its intriguing, possibly protective role in dopaminergic cell death due to a toxic cause,[18,19] and the original dopamine replacement drug, levodopa, both given at the earliest clinical expression of the disease process (when at best, only 20% of dopaminergic neurons may still be functionally intact), seems a most reasonable approach as initial symptomatic therapy in de novo patients with PD.

Ideomotor Apraxia in Huntington's Disease

Paul A. Shelton, MD, David S. Knopman, MD

• The pattern of movement errors in ideomotor apraxia suggests an abnormality in selection and sequencing of component movements. Individuals with Huntington's disease were evaluated prospectively for the presence of apraxia, and aspects of motor and cognitive function were correlated with apraxic errors. Based on a conservative apraxia rating, ideomotor apraxia occurred in three (33%) of nine patients with a mean duration of disease of 10.4 years. Only two (22%) individuals made no apraxic errors, however, and the group as a whole made apraxic errors in 26% of movements. Apraxia was associated with errors in imitation of nonsymbolic movements but not with errors in recognition of gestures. It correlated significantly with duration of disease and with progressive abnormalities of posture but not with other individual aspects of elementary motor or cognitive function. These associations indicate that apraxia in Huntington's disease may be due primarily to involvement of subcortical motor structures rather than cerebral cortex.

(*Arch Neurol.* 1991;48:35-41)

Ideomotor apraxia is a disorder of the performance of previously learned complex movements that cannot be ascribed to deficits in elementary motor function.[1,2] The performance of movements in an appropriate context and with real objects is characteristically better than propositional performance in individuals with ideomotor apraxia. Errors occur in symbolic movements, or gestures and pantomime, and it has been considered a disorder of symbolic behavior related to language (Goldstein, 1948). However, the imitation of novel nonsymbolic movements and the spontaneous production of previously learned nonsymbolic skilled movements, such as the use of a real tool, are also abnormal.[3,4] Ideomotor apraxia is highly associated with aphasia due to lesions of the language-dominant hemisphere, but both aphasia and apraxia may occur in isolation, suggesting that rather than being related disturbances of symbolic behavior, language and the production of learned movements are independent functions mediated by similar cerebral areas.

Several studies indicate that the imitation of nonsymbolic novel movements by apraxic subjects may actually be worse than imitation of symbolic movements and that this pattern may occur more often with lesions of the nondominant hemisphere.[3,5,6] Furthermore, error patterns in individuals with right or left hemisphere lesions do not appear to differ.[7] Together these findings suggest that ideomotor apraxia is a disorder of the formulation of complex and previously learned actions rather than of the ability to use symbols per se; ie, it is a disorder of motor programming.[1] Error pattern analyses for previously learned movements in patients with ideomotor apraxia suggest abnormal integration of component movements into a complete and appropriately timed sequence.

Based on evidence that the basal ganglia are involved in the formulation and coordination of complex previously learned motor routines, and on the evidence that ideomotor apraxia is a disorder of motor programming rather than symbol use per se, it is reasonable to expect disorders primarily affecting the basal ganglia to cause ideomotor apraxia. Therefore, we prospectively evaluated individuals with Huntington's disease (HD) for the presence of ideomotor apraxia.

SUBJECTS AND METHODS

Subjects

Apraxia was evaluated in three groups of individuals: patients with HD, a control group with senile dementia of the Alzheimer type (SDAT), and a group of normal controls. The individuals with HD had all been evaluated at the HD clinic at Hennepin County (Minn) Medical Center. Diagnosis was assigned on the basis of neurologic and behavioral symptoms and signs, appropriate family history, findings of computed tomography or magnetic resonance imaging, and the natural history of the disorder.[8-12] Criteria for diagnosis included the presence of chorea, dystonia, rigidity, and akinesia or the gradually progressive characteristic disorder of voluntary movement, not present at birth and of insidious onset. Emotional disturbances, memory loss, and other cognitive disturbances were present in most subjects. All patients seen in the clinic by the investigators during the study period and individuals seen previously and residing in a personal care center were eligible. Informed consent was obtained from 12 patients with HD and their legal guardians.

The subjects with SDAT were selected from among residents in a different personal care center. All residents with an admitting diagnosis of senile dementia, primary degenerative dementia, or Alzheimer's disease for whom consent could be obtained were screened using NINCDS-ADRDA criteria for SDAT.[13] Of 12 such individuals, only six met the criteria for probable SDAT. The SDAT control group was chosen because apraxia is known to occur in the disease and is associated with pathologic changes in the cortex. Measures of praxis and cognitive function used in the

study were validated in this group.

Finally, 20 normal controls were selected from medical and orthopedic inpatient services. The age range included that of both patient groups, and none of the subjects had evidence of active central nervous system disease. Exclusion criteria included a history of stroke, dementia, or functionally significant memory impairment; moderate or severe hypertension; diabetes; syncope; brain tumor or systemic malignancy; significant head trauma; recurrent seizures; central nervous system infection; collagen vascular disease; and the use of psychoactive medications.

Table 1.—Auditory Comprehension Test*

1. Raise your hand.
2. Turn your head, then close your eyes.
3. Clap your hands, then look at the floor and touch your nose.
4. Touch the paper clip.
5. Touch the coin, then the pen.
6. Touch the fork, then the keys, and then the pen.
7. Touch the smallest object.
8. Put the pen between the coin and the keys.
9. Touch the pen with the fork.
10. Put the keys on top of the paper clip and pick up the coin.
11. Touch all of the objects.
12. Instead of the keys, pick up the pen.

*Based on an array of five objects: pen, fork, paper clip, penny, and keys. Scoring: 1, correct response; ½, repeat command once, correct response; and 0, incorrect or no response.

Procedures

The evaluation of all patients included a complete neurologic examination and history regarding the onset of illness, initial manifestations, and course. The family history was obtained from the patient's spouse, sibling, or occasionally a parent. The patient's age at onset of the first manifestations of HD or SDAT, duration of illness at the time of entry into the study, years of education, occupation, sex of the patient from whom the disease was inherited, and medications were recorded. Family history and formal pedigree were obtained by a geneticist, and vertical transmission, often with affected sibs, was documented. In only one individual with HD was the propositus the sole affected member in the pedigree, and this subject was subsequently excluded from the analysis of the results of the study (HD patient 11). Only one subject with probable SDAT had a positive family history with a mother who became demented at 70 years of age (SDAT patient 6).

Overall functional disability in all subjects was assessed according to Shoulson and Fahn's (1979) staging system for HD, in which individuals at stage 1 are employed at their usual level, and at stage 5 require total institutional care.[14]

A 14-item quantitative motor examination[10,15] was used to assess motor disability in patients with HD, and the scores on nine major aspects of motor function, scored 0 through 3 or 0 through 4 (ie, chorea, dystonia, rigidity, bradykinesia, dysdiadochokinesia, posture, speech, saccadic eye movement, and impersistence) were summed to create a composite score, the motor disability score, where a score of 0 indicates normal motor function and 32 indicates the maximum degree of motor dysfunction. Chorea was assessed in six different body segments and under five different conditions, giving a total of 30 scores per subject. To facilitate comparisons, an average measure of degree of chorea was derived from these data, the mean chorea score. This was the average of right and left upper limb and bucco-orolingual chorea in both seated and stressed conditions, with a score of 0 indicating the absence of chorea and 4 indicating a marked degree in terms of both amplitude and frequency.

An estimate of the degree of dementia was obtained with the Mini-Mental State examination (MMSE).[16] Other neuropsychological measures were designed to evaluate aspects of cognitive function that are of theoretical importance for the organization of symbolic motor behavior. A test of auditory comprehension similar to the Token Test[17] was devised, with easily discriminable test items (objects that were used in the formal apraxia test) and with less memory loading (Table 1). The 12 items included tests of single word comprehension, two- and three-stage sequential commands, and five items testing syntax comprehension.

Ideomotor apraxia was assessed in a standardized manner. Abnormal movements were scored as apraxic if (1) no obvious choreiform or dystonic movements coincided with the response; (2) the response did not correct after verbal instructions were repeated once (eg, if the subjects used a body part as object, they were instructed to pretend that they were actually holding the object); (3) comprehension of the command could be documented by having the subjects repeat the instructions or select the tool they were asked to use from a set of six; and (4) if the error conformed to one of the predetermined apraxic patterns. Error types were defined according to symbolic content, distal and proximal movements, postural fixation, and errors in timing and sequence of movements. Eight error types were thereby defined: (1) symbolic content errors, where the target movement was a recognizable gesture or pantomime but not appropriate for the gesture or tool requested; (2) body part-as-object, where the subject substitutes his or her own hand for the object rather than manipulating an imaginary object; (3) hand posture errors, where the configuration of the hand is inappropriate or fails to accommodate the imagined tool, but the movement of the limb is recognizable and appropriate for the target gesture or tool; (4) spatial orientation errors, a movement error where the hand posture or grip is correct but the movement is not directed to an appropriate target or is otherwise improperly oriented in space; (5) motor sequencing errors, where components of a limb movement are carried out in an improper or inconsistent order; (6) perseverative errors, where the immediately preceding gesture or pantomime is repeated; (7) onomatopoeic errors, where the verbal description of the action is substituted for the actual movement, eg, "blow"; and (8) imprecision errors, where the movement is inaccurate but the essential aspects of the action are recognizable.

Table 2.—Ideomotor Apraxia Test Items

Transitive limb
  1. Use a key
  2. Use a hammer
  3. Comb your hair
  4. Brush your teeth
  5. Screwdriver
  6. Scissors
  7. Use an eraser
  8. Throw a ball
  9. Flip a coin
  10. Stir with a spoon
Intransitive limb
  11. Wave goodbye
  12. Hitchhike
  13. Salute
  14. Motion come here
Buccofacial
  15. Blow out a match
  16. Sip through a straw
  17. Stick out your tongue
  18. Blow a kiss
  19. Cough
Axial
  20. Roll over in bed, or stand up, or turn your head

Complete failure to carry out the command may be a manifestation of ideomotor apraxia, but, for the purposes of this study, such errors were not scored because of the difficulty in documenting that they were indeed due to apraxia rather than to a failure to fully comprehend the instructions or to attend to the task. A priori, only body part-as-object errors, hand posture errors, and content errors as defined above were considered to be unequivocal apraxic errors, because the target action could be identified in each instance.

The formal ideomotor apraxia test included 20 test items: 10 transitive limb, four intransitive limb, five buccofacial, and one axial movement, which varied depending on the position of the subject at the time of examination (Table 2). The test was composed of four parts: (1) subjects first responded to a verbal command (propositional); (2) the examiner demonstrated three movements including the correct gesture and the subject identified the correct movement verbally, by number or by pointing; (3) subjects imitated the correct gesture, performed by the examiner, and any improvement in the response of the patient compared with propositional performance was recorded; and (4) subjects used the real object.

Three measures of apraxia were derived. The clinical rating was the assessment of the presence of apraxia in the standard screening neurologic examination performed at the time of entry into the study. When present, apraxia was rated as (1) mild, (2) moderate, or (3) severe, based on the frequency of errors and the occurrence with real objects. Second, a conservative estimate of the presence and degree of apraxia, the objective apraxia rating, was derived from the results of the formal apraxia test. Only unequivocal apraxic errors were considered in this rating, and all other errors were recorded but not scored. Subjects were assigned an apraxic rating only if they made three or more unequivocal apraxic errors, and the degree of apraxia was graded as follows: grade 1, three to five errors; grade 2, six to 10 errors; grade 3, 11 to 15 errors; and grade 4, 16 to 20 errors in the 20-item test. Third, all apraxic errors, major and minor, but excluding those scored as imprecision errors, were totaled for the total apraxic errors. Similarly, the total number of transitive and intransitive errors and of the total limb and buccofacial errors were analyzed.

An independent measure of the ability to imitate movement was devised to eliminate the influence of cuing inherent in the repeated exposure to the movements of the apraxia test and to compare ideomotor apraxia with impairment of performance of nonsymbolic movements. The items were similar to those used by De Renzi et al.[3,5] The examiner sat facing the subject and demonstrated 10 items that included four symbolic hand and finger movements (A-OK, victory, no-no, come here) and eight nonsymbolic novel movements, both categories including both fixed postures and movement sequences. The response was scored as correct or incorrect, and the total correct was recorded as the movement imitation score. Subjects were also asked to imitate Luria's two- and three-step motor sequences.

The normal controls were evaluated with the MMSE and the auditory comprehension, apraxia, movement imitation, movement recognition, and Luria's motor sequencing tests. The scores of the three study groups were compared by repeated measures analysis of variance for age, education, MMSE score, auditory comprehension score, all measures of ideomotor apraxia, and movement imitation. The patient groups were also compared in terms of duration of disease and functional disability rating. Significant differences thus identified by analysis of variance were evaluated by two-sample t tests with separate variance in a pairwise manner.

Finally, the scores of the HD group on all measures of ideomotor apraxia were compared by calculating Spearman rank correlation coefficients. Correlation coefficients were similarly calculated between the apraxia scores and all other measures of motor and cognitive function.

RESULTS

The clinical characteristics of the 12 subjects with HD are indicated in Tables 3 and 4. As the tables demonstrate, the HD group presents a broad range of disability, and the pattern of motor involvement is characteristic of the disease in general. One individual with HD had the predominantly rigid form of the disease (8%). No difference in age of onset was demonstrated according to sex of the affected parent, the mean age at onset being 39.0 years for male inheritance and 38.7 years for female inheritance (data were unavailable for two subjects). The HD and SDAT groups differed significantly in age (F[1,17] = 18.45; $P < .002$) and age at onset (mean, 73.6 years for SDAT group), as expected, but the mean ages were typical of the respective disorders. The groups were similar in overall functional disability rating (mean, 4.0 for SDAT group), and both were in midcourse according to the respective mean durations of disease (mean, 5.6 years for SDAT group).[8-11] Because of the age disparity in the patient groups, normal controls were selected with a range of ages encompassing both patient groups. The resulting control group had a mean age differing significantly from either patient group. The normal subjects were divided into two groups (n = 10) according to age: those younger than 65 years and those 65 and older (mean age (±SD), 57.9 ±5.93 and 73.4 ± 4.48, respectively). The mean age of the HD group was less than 2 SD from that of the younger normal subgroup, and, similarly, the age of the SDAT group was not significantly different from that of the older normal subgroup. These normal subgroups did not differ with respect to MMSE scores ($P > .29$), comprehension ($P = 1.0$), praxic errors ($P > .62$), movement recognition ($P > .56$), movement imitation ($P > .72$), and motor sequencing ($P > .30$), and they were therefore combined for all subsequent comparisons with the patient groups.

Two subjects (HD patients 10 and 11) were excluded from subsequent analysis because comprehension of commands in the apraxia test could not be documented and the occurrence of ideomotor apraxia could not be adequately evaluated. One subject (HD patient 12) was excluded because she refused to complete all tests. Most subjects with HD were treated with neuroleptic medication, but there was no correlation between use or dose of medication and the presence or degree of bradykinesia or apraxia. Specifically, HD patient 1 was taking no medications. The total daily doses (in milligrams) of other medications were as follows: HD patient 2, clorazepate dipotassium (3.75); HD patient 3, haloperidol decanoate (4.5) and lorazepam (6); HD patient 4, haloperidol (2), oxybutynin chloride (15) and levothyroxine sodium (0.2); and HD patient 5, chlorpromazine hydrochloride (75) and molindone hydrochloride (30); and HD patient 8, haloperidol (10) and alprazoloam (2); HD patients 6, 7, and 9 took only haloperidol at doses of 6, 40, and 5 mg/d, respectively.

The results of the tests of praxic function for the nine remaining subjects with HD are indicated in Table 5, and a comparison of results for HD, SDAT, and normal control groups are presented in Table 6. According to the objective apraxia rating, the most conservative measure of apraxia in this study, three (33%) of nine patients with HD and one (17%) of the six patients with SDAT but none of the normal controls were apraxic. The proportion of apraxic patients with SDAT was lower than that generally reported, which may be due to the moderate degree of cognitive impairment in the group as a whole and to the strict criteria established for the presence of apraxia in this study. According to the analysis of variance, the patient groups differed from the normal controls significantly in MMSE scores (F[2,32] = 51.30; $P < .001$), auditory comprehension (F[2,30] = 22.28; $P < .001$), total apraxic errors (F[2,32] = 9.32; $P < .001$), motor sequencing (F[2,32] = 12.03; $P < .001$), and education (F[2,32] = 3.91; $P < .05$) but not in movement recognition (F[2,32] = 0.47; $P > .6$) or movement imitation (F[2,31] = 2.19; $P > .1$). Post hoc analysis of these results with two-sample t tests indicated that only the patients with HD differed from the normal controls in total apraxic errors ($t = 2.73$; $df = 8.1$; $P < .026$) and years of education ($t = 2.85$; $df = 19.4$; $P < .010$). Both the HD and SDAT groups differed from the normal controls in MMSE, comprehension, and motor sequencing scores (Table 6).

As a group, the patients with HD made apraxic errors in 26% of movements (total apraxic errors, 6.0 of 20) and subjects with SDAT made apraxic movements in only 12.5% of movements (total apraxic errors [mean], 2.5 of 20). The most frequent error type in patients with HD was hand posture errors (33%), followed by body part-as-object (26%), content (17%), spatial orientation (11%), and motor sequencing errors, onomatopoeic and imprecision errors each accounting for 4% of errors. It may be argued that in the setting of an established basal ganglia disorder only body part–as-object or content errors may be reliably distinguished from more elementary disorders of movement. When only these types of errors were analyzed, the patients with HD still made significantly more errors than did control subjects (F[1,27] = 13.635; $P < .001$).

All measures of apraxia were highly correlated with one another, including the most and least conservative measures, the objective rating, and the total errors (Spearman, $r = .86$; $P < .003$). The clinical rating correlated with the objective apraxia rating ($r = .92$; $P < .0004$), the total apraxic errors ($r = .84$; $P < .0042$), the number of transitive errors ($r = 0.85$; $P < .0033$), and the number of intransitive errors ($r = .71$; $P < .032$). The difference between patient groups in the frequency of occurrence of apraxia was not significant (total apraxic errors, F[1,14] = 2.32; $P > .15$). There was also no difference between the groups in transitive (F[1,14] = 1.66; $P > .22$) or intransitive (F[1,14] = 3.05; $P > .10$) movements.

The degree of apraxia in individual subjects with HD correlated significantly with the duration of HD (Fig 1) (total apraxic errors, $r = .68$; $P < .043$), posture ($r = .79$; $P < .011$) and move-

ment imitation (both nonsymbolic and symbolic movements) (transitive errors, $r = .73$; $P < .041$) (total apraxic errors, $r = .68$; $P < .065$). There was also a trend between degree of apraxia and degree of overall motor disability, ie, the composite motor disability score (transitive errors, $r = .65$; $P < .059$) (total apraxic errors, $r = 0.59$; $P < .096$) and functional disability rating (transitive errors, $r = .65$; $P < .059$) (total apraxic errors, $r = .62$; $P < .075$). There was no correlation between degree of apraxia and degree of chorea (total apraxic errors, $r = .28$; $P > .46$), dystonia ($r = .25$; $P > .50$), rigidity ($r = .17$; $P > .65$), bradykinesia ($r = .50$; $P > .16$), dysdiadochokinesia ($r = .22$; $P > .55$), speech ($r = .29$; $P > .44$), extraocular movements ($r = .48$; $P > .18$), or motor impersistence ($r = .46$; $P > .20$).

Finally, there was no correlation between the degree of apraxia in HD and measures of cognitive function including auditory comprehension (total apraxic errors, $r = .62$; $P > .13$) and MMSE ($r = .24$; $P > .52$). The subjects with HD performed uniformly well in movement recognition, and no subject was able to perform Luria's motor sequences.

COMMENT

The principal finding of this study is that ideomotor apraxia occurs in at least one third of individuals with HD. It is possible that the actual frequency is higher, as a rather conservative rating system was used in this study. In addition, those individuals who were severely impaired were excluded from the analysis, and it was impossible to determine the degree to which their failure to respond during testing resulted from apraxia as opposed to a failure to comprehend or attend to the commands. Seven (78%) of nine patients with HD made at least two apraxic errors, and it is possible that unequivocal apraxia would develop in such individuals with progression of the disease. If the maximum number of errors made by any normal subject on the apraxia test (one apraxic error) is accepted as the cutoff score between apraxic and nonapraxic subjects, two errors indicating the presence of apraxia (> 3 SD from the control group mean), then all of these individuals are apraxic. Similarly, three (50%) of the subjects with SDAT would be scored as apraxic.

Ideomotor apraxia has not previously been studied in HD. This is perhaps surprising because a variety of cognitive disorders including aphasia and neglect have been shown to result from subcortical as well as cortical lesions. Huntington's disease is associated with a variety of abnormalities in voluntary motor function, and involuntary movements may degrade or obscure target movements, complicating the interpretation of apraxia. This may in part explain the lack of information in the literature. The exclusion of deficits in elementary motor function is generally required for the diagnosis of apraxia. However, certain error types are characteristic of ideomotor apraxia and are recognizable even when degraded. For example, the use of a body part as object clearly identifies the target movement and indicates an error in the selection or symbolic content of the movement, permitting the demonstration of apraxia. In this study, apraxic errors were analyzed and, for the above reasons, only unequivocal apraxic errors were used in the assignment of apraxic status.

The pattern of apraxic errors in the patients with HD was similar to errors in apraxia following focal cerebral lesions.[7,18] The most common errors were body part-as-object, hand posture, spatial orientation, and content errors. In subjects with single unilateral cerebral infarctions, Rothi et al[18] found that the most frequent errors were body part-as-object, internal configuration (similar to hand posture errors here), external configuration orientation and external configuration movement (which together are similar to spatial orientation errors here), and content errors. The similar pattern in HD indicates that the errors were apraxic in nature and unrelated to chorea, dystonia, tremor, ataxia, or paresis. The patients manifested varying degrees of each of these movement disorders, but the presence of apraxia did not correlate with any of these, nor with bradykinesia or rigidity as assessed independently from the apraxia tests. Errors in the symbolic content of the movements and the fact that the movement errors were most frequent in the propositional setting and characteristically resolved when subjects used the real object also suggest that these errors were not due to abnormalities of elementary motor function.

Two varieties of ideomotor apraxia have been differentiated based on the ability of apraxic individuals to recognize and visually discriminate movements.[19] Those individuals with posterior parietal lesions or fluent aphasia are impaired in movement recognition compared with subjects with anterior lesions or nonfluent aphasia. It was proposed that the impairment of movement recognition results from destruction of visuokinesthetic engrams in the dominant inferior parietal cortex that encode the spatial characteristics, sequence, and timing of component movements. In HD, apraxia is therefore of the anterior type, with preservation of movement discrimination. This is consistent with the known relationships between the striatum, the initial and major focus of pathologic changes in HD, and the frontal association cortices. Early cognitive deficits in HD include decreased concentration, apathy, impairment of spontaneous initiation of activity, poor social judgment, organization and planning of sequential tasks, decreased verbal fluency, maze tracing, visual tracking, and abnormalities of narrative language or discourse, all suggesting abnormalities of frontal lobe function.[20-25] A similar pattern of deficits occurs following focal caudate infarction.[26]

The striatum is functionally associated with frontal lobe structures. While the basal ganglia receive afferents from virtually every cortical area, the putamen appears to be part of a functionally segregated circuit, receiving its principal input from primary motor, supplementary motor, premotor, and somatosensory cortices. Its principal output is to the supplementary motor cortex via ventral anterior and ventral lateral thalamic nuclei. The caudate receives its principal input from the frontal association cortex, and its output is to dorsolateral prefrontal, orbitofrontal, and anterior cingulate cortices.[27] The basal ganglia appear to be involved in nearly all types of movement, including self-paced or internally generated spontaneous movements and stimulus-triggered movements, including both ballistic and slow pursuit movements.[27-29] The supplementary motor area appears to be involved in the initiation of movement and in motor planning, as supplementary motor area lesions result in akinesia and mutism, and cerebral blood flow and electrophysiologic activity of the supplementary motor area increase in a specific manner preceding voluntary movement.[30-34] Furthermore, bilateral ideomotor apraxia has been demonstrated in association with lesions of the left supplementary motor area.[35] It is important to note that putaminal neuronal activity similarly changes in relation to movement instructions in preparation for movement, and the basal ganglia may therefore have a role in motor planning similar to that of the supplementary motor area.[36]

Individuals with Parkinson's disease characteristically have difficulty with initiation of movement and in sustaining multiple simultaneous actions, but responses may be substantially improved with external cues.[37] Marsden[38] proposed that the basal ganglia are involved in "the automatic execution of learned motor plans," requiring the sequential or concurrent operation of a number of simple motor programs. More recently, Thompson et al[39] have demonstrated similar difficulty in the performance of sequential and concurrent movements in HD. Ideomotor apraxia in HD may therefore be caused by abnormalities in the interaction between the abnormal basal ganglia and unaffected premotor cortical structures more commonly associated with apraxia, resulting from a dissolution of such aspects of motor programming. This would indicate further that basal ganglia processing is required for the performance of symbolic movements and that the interaction between parietal cortex and frontal association cortex alone is insufficient. The subjects with SDAT were less apraxic and more demented than those with HD (according to MMSE and auditory comprehension scores), a double dissociation in cognitive deficits. This finding suggests that the mechanism of apraxia in HD differs from the disruption of cortical processing presumed to be the cause of apraxia in SDAT.[40]

On the basis of this study, it cannot be determined whether the apraxia was due to involvement of frontal cortex or to involvement of subcortical structures alone. In early stages of HD, the caudate head is selectively involved and progresses to involve the putamen, the globus pallidus, and subthalamic and certain thalamic nuclei. In late stages of the disease, structural changes in the cerebral cortex have been documented in some individuals, primarily neuronal loss and mild gliosis in deeper layers of the frontal cortex.[41] Several of the subjects in the present study who made apraxic errors were only mildly impaired in terms of cognitive function (HD patients 7, 8, and 9). Fluorodeoxyglucose positron emission tomography and computed tomographic studies have demonstrated that early dementia in HD is associated with hypometabolism of the caudate head but not with atroph or hypometabolic changes in the cerebral cortex.[42] It appears, therefore that ideomotor apraxia occurs in H at a stage when cortical structures ar not implicated in the degenerative process, lending support to the hypothesi that apraxia may result from basa ganglia lesions alone.

Ideomotor apraxia is most often du to focal lesions of the dominant inferior parietal lobe and is therefore associated with disturbances of languag comprehension. The preservation o auditory comprehension and the lac of correlation between the occurrenc of apraxia and comprehension tes scores in this study at first suggeste that subcortical disease was responsible for the apraxia. As indicated above however, ideomotor apraxia also results from lesions restricted to premotor association cortex or to subcortical white matter connections between premotor and inferior parietal areas. As there was no independent discrete measure of frontal association cortex function, the possibility of frontal, exclusive of parietal, cortical involvement remains unresolved.

Mild ideomotor apraxia was previously reported in association with focal infarction of basal ganglia, thalamus, and internal capsule in either the right or the left hemispheres. An analysis of apraxic errors was not performed in this study,[43] however, and a comparison with the pattern of ideomotor apraxia in the present study is not possible.

To conclude, it appears that certain aspects of the apraxias, which are considered to be disorders of higher cortical function, result from the disruption of basal ganglia input. In this regard, it has been demonstrated that putaminal activity increases in relation to instructions for movement alone and that the basal ganglia play a significant role in the initiation of voluntary movement.[34,35] Error pattern analyses indicate that a majority of apraxic errors are not errors of symbolic content but represent a failure to combine individual proximal and distal limb movements either concurrently or in sequence. This is consistent with the common abnormalities of motor control seen in basal ganglia disorders.[27-38]

The authors would like to thank the administrative and nursing staff at Metro Care Center, Minneapolis, Minn, and Langton Lake Place, St Paul, Minn, for their assistance in evaluating patients. We are also grateful to Berel Westphal of the Department of Neurology, Hennepin County (Minn) Medical Center, for her assistance in identifying and evaluating subjects.

Initial Therapy of Patients With Wilson's Disease With Tetrathiomolybdate

George J. Brewer, MD; Robert D. Dick; Vilma Yuzbasiyan-Gurkin, PhD;
Roberta Tankanow, MS; Anne B. Young, MD; Karen J. Kluin, MS

• Patients with Wilson's disease who present with acute neurological symptoms often become clinically worse when initially treated with penicillamine. Other available anticopper drug therapies do not appear to offer a solution to this treatment problem. We are developing and evaluating a new drug, ammonium tetrathiomolybdate for this purpose. Theoretically, tetrathiomolybdate has optimal properties, including an immediate blockade of copper absorption and the property of forming complexes with copper in the blood, rendering the copper nontoxic. In this article, we present results from six patients treated with tetrathiomolybdate for up to 8 weeks as initial therapy. None of the five patients who had presented with acute neurological symptoms worsened. Also presented are methods of assay, preliminary stability studies, and methods of evaluating therapeutic end points with respect to copper metabolism.

(*Arch Neurol.* 1991;48:42-47)

The anticopper therapy of patients presenting with symptomatic Wilson's disease can be broken down as occurring in two phases. The first is the initial treatment phase, generally thought of as the period when toxic copper levels are brought under control so that further copper toxicity is abated. The second is the maintenance treatment phase, which is the lifelong prevention of the reaccumulation of copper to toxic levels. Any one of three drugs—zinc, penicillamine, or trien—can be used for maintenance therapy with complete efficacy.[1,2] These three drugs differ for this use only in the number and severity of side-effects and in the extent of recorded experience. In contrast with this relatively comfortable situation for maintenance therapy, a satisfactory approach for the initial treatment of symptomatic patients has not been worked out, in our opinion.

This hiatus in therapy is most apparent for the patient who presents with neurological symptoms from Wilson's disease. We have anecdotally observed patients becoming much more severely affected neurologically when initially treated with penicillamine. A retrospective survey revealed that 13 of 25 patients presenting with neurological symptoms worsened within the first few weeks of therapy with penicillamine, and that six of these patients never recovered to the pretherapy baseline.[3] The mechanism of this penicillamine-induced neurological worsening is not clear but may involve redistribution of copper from other parts of the body into the brain, or within intracellular compartments.

At least theoretically, zinc therapy also does not appear to be the answer for this type of patient. It acts slowly and produces only a very modest negative copper balance.[4,5] It seems possible that the disease could progress to a certain extent during the several months that it takes to bring copper toxicity under control. Indeed, in one of three neurologically affected patients whom we treated with zinc, tremor did seem to progress over the first few months of therapy. There is very little experience with the third drug therapy, trien. Since its mechanism of action is somewhat similar to penicillamine, it may be subject to the same problem of neurological worsening.

We believe that ammonium tetrathiomolybdate may provide an answer for the initial treatment of the neurologically affected patient. This drug has two anticopper mechanisms of action.[6-9] One mechanism involves complexing copper, together with food proteins, in the gastrointestinal tract, preventing absorption of copper. The second mechanism is that absorbed tetrathiomolybdate forms complexes with copper and albumin in blood, rendering the copper unavailable for cellular uptake, and, therefore, removing it from toxic pools. Because of these promising properties, we have carried out pilot work using tetrathiomolybdate for the initial treatment of neurologically affected patients. Herein we report our observations with the first six patients whom we have treated with tetrathiomolybdate.

PATIENTS AND METHODS

Patients

The six patients involved in this study all had Wilson's disease, as established by criteria summarized in Table 1. The first five patients listed in Table 1 presented with acute neurological symptoms, as summarized in Table 1. The sixth patient (No. 38) had originally presented with neurological disease but had been treated for several years with penicillamine and later with zinc. Inexplicably, she stopped all treatment for many months and then presented to us with a copper status that was out of control. Her liver-derived serum enzyme levels were significantly elevated, compared with prior values. Because of concerns that neurological deterioration might develop at any time, we elected to treat her initially with tetrathiomolybdate. In three of the first five listed cases in Table 1 (cases 56, 63, and 68), the initial treatment was with tetrathiomolybdate. Patients 61 and 79 had been treated briefly with penicillamine and, because of concerns that their conditions were deteriorating, were referred to us for treatment with tetrathiomolybdate. All patients who participated in this study were hospitalized in the Clinical Research Center of the University of Michigan Hospital, Ann Arbor. Most patients were admitted for the entire time they received tetrathiomolybdate. All patients who participated in this study gave written informed consent. This research was carried out according to the principles of the Declaration of Helsinki (Finland) and approved by the Committee on the Use of Humans as Experimental Subjects of the University of Michigan.

Materials

Tetrathiomolybdate was purchased from Aldrich Chemical Co, Milwaukee, Wis, in a form suitable for human administration. It was stored in bulk form, anaerobically, protected from light, and at room temperature (*standard bulk storage*). At the time of admission of a patient who was to receive therapy with tetrathiomolybdate, the drug was weighed out in appropriate amounts

Table 1.—Initial Clinical and Laboratory Observations

Patient No.	Sex	Age at Tetrathiomolybdate Initiation, y	Kayser-Fleischer Rings	Plasma Ceruloplasmin, mg/L	Plasma Copper, μmol/L	Copper in Liver, μg/g Dry Weight	Copper in Urine, μmol/d	Neurological Symptoms	Comment
56	M	36	Present	131	9.9	1621	3.4	Dysarthria; gait abnormalities; tremor; cerebellar; discoordination	...
61	M	16	Present	<10	7.5	1411	2.1	Dysarthria; tremor; dystonia; drooling; gait abnormalities	Treated initially with penicillamine for 6 wk
63	M	24	Present	130	12.4	391	3.4	Dysarthria; rigidity; gait abnormalities; dystonia	...
68	M	22	Present	<10	7.5	428	5.0	Dysarthria; rigidity; gait abnormalities; dystonia; tremor	White matter lesions on magnetic resonance imaging; developed seizures
79	M	32	Present	72	9.4	1228	5.2	Dysarthria; tremor; gait abnormalities; rigidity; dystonia	Treated initially with low doses of penicillamine for 4 wk
38	F	24	Present	<10	7.5	781	7.6	Dysarthria; gait abnormalities; drooling	Special case; patient receiving maintenance therapy who quit therapy and developed high copper values in urine

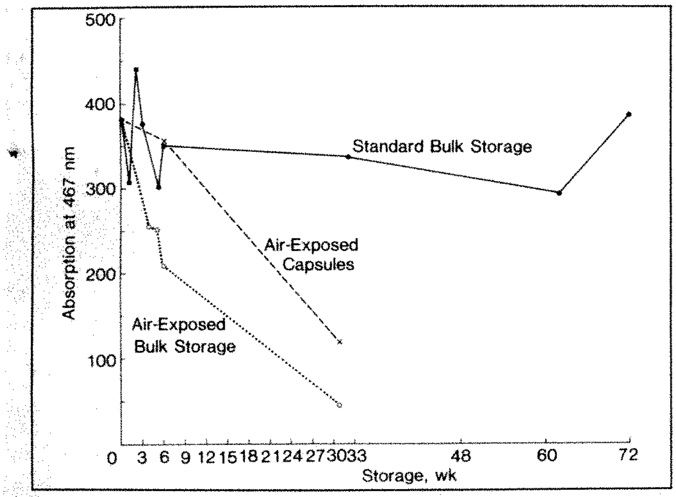

Fig 1.—For standard bulk storage, tetrathiomolybdate was kept in 100-g brown, sealed bottles at room temperature. For air-exposed bulk storage, a few grams of the powder were kept in a bottle with the top off at room temperature. For air-exposed capsules, capsules were kept in a bottle with the top off at room temperature. For assay, 10 μg of the drug was placed in 1.0 mL of distilled water, and absorption measured at 467 nm in a spectrophotometer (Gilford 2400S, Gilford Instrument Laboratories Inc, Oberlin, Ohio).

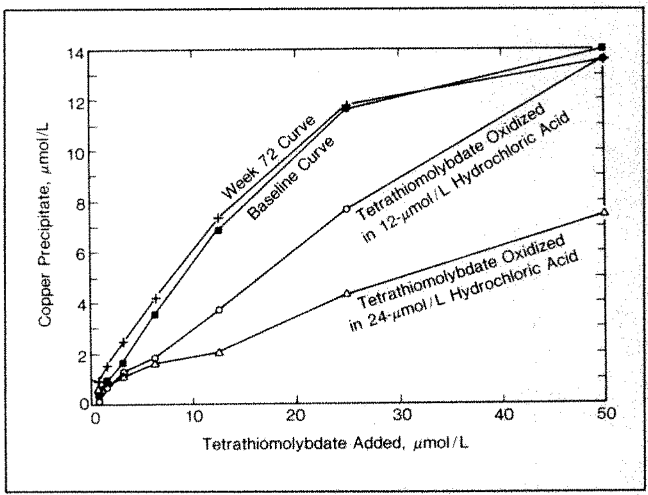

Fig 2.—This biological assay was carried out by adding the indicated amount of tetrathiomolybdate to 2.0 mL of 5.0 mmol/L-Hepes buffer containing 15 μmol/L of copper acetate and 150 μmol/L of human albumin. The mixture was allowed to stand for 15 minutes at room temperature. Then 2.0 mL of the mixture was mixed with 2.0 mL of the trichloroacetic acid solution, such that the final concentration of trichloroacetic acid was 5%. This mixture was shaken for 15 seconds in a Vortex mixer and then centrifuged at 1500 *g*. The copper concentration in the supernatant was assayed and subtracted from that added to determine the amount of copper precipitated. As a control, to show loss of tetrathiomolybdate biological activity under conditions of oxidation, tetrathiomolybdate treated with either 12 or 24 μmol/L of hydrochloric acid was also assayed.

Table 2.—Tetrathiomolybdate Therapy Data

Patient No.	Weight, kg	Final Dose		Dose Regimen Amount, mg*		Days Until Closure of Copper-Molybdenum Gap
		mg/d	mg/kg	With Meals	Between Meals	
56	97	150	1.6	20	30	15
61	62	180	2.9	20	40	17
63	87	210	2.4	30	40	11
68	51	150	2.9	20	30	14
79	93	220	2.4	20	60-60-40	29
38	45	90	2.0	10	20	8

*The tetrathiomolybdate was administered three times daily with meals, and three times daily between meals.

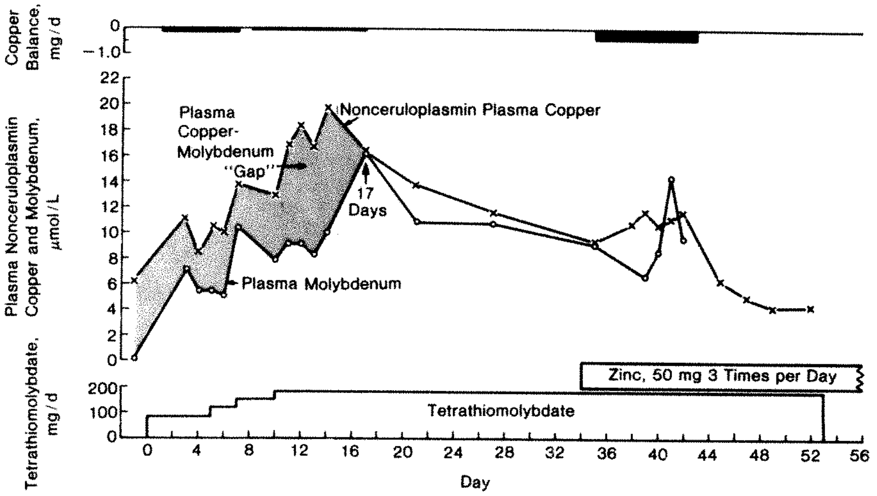

Fig 4.—Results of treatment of patient 61 with tetrathiomolybdate.

and placed in capsules by one of us (R.T.). Depending on the patient and dose prescribed, capsules contained 10, 20, 30, or 40 mg. The dose of drug was individualized in each case as experience was gained (Table 2). Details are provided in the "Results" section.

Methods

The stability and potency of tetrathiomolybdate was evaluated in several ways. The parent molecule has an absorption peak at 467 nm,[10] and this was followed over time (methodological details in the legend to Fig 1). In addition, a bioassay was developed that depended on rendering a stoichiometric amount of copper insoluble in trichloroacetic acid in the presence of albumin (methodological details in the legend to Fig 2). We also performed special studies examining the rate of degradation under conditions of patient usage and under conditions that were anticipated to make the drug degrade. These conditions will be defined in the "Results" section and in the figure legends.

End points for our therapeutic objectives related to copper needed to be defined to determine the dosage required. We had two proximal therapeutic objectives. One was to block absorption of copper in the gastrointestinal tract as soon as possible after therapy began. This end point was evaluated by established methods determining the absorption of orally administered copper 64[11] and by evaluating copper balance.[4,5] The second objective was to "neutralize" the potentially toxic copper levels in the blood as rapidly as possible. By *neutralize* we mean the binding of the potentially toxic copper to tetrathiomolybdate-albumin complexes, which renders the copper unavailable for cellular uptake. This effect was evaluated as follows: First, the total plasma copper and the ceruloplasmin activity were determined, and the calculated amount of ceruloplasmin-bound copper (3 µg of copper per milligram of ceruloplasmin) was subtracted from the total plasma copper level to determine the nonceruloplasmin plasma copper (NCPCu) level. Ceruloplasmin-bound copper is viewed as nontoxic. The NCPCu level is the potentially toxic copper and is the copper that needs to be "neutralized" by tetrathiomolybdate therapy. We then determined the total molybdenum content of the plasma and examined the stoichiometry of molybdenum to NCPCu, which should be 1:1 when all NCPCu is complexed to tetrathiomolybdate. Copper and molybdenum were assayed by atomic-absorption spectrophotometry (IL 451, Instrumentation Laboratory Inc, Wilmington, Mass). In one instance, an effect of treatment on mean excretion of copper in urine was evaluated for statistical significance using the paired *t* test.

It was critical during this study to determine the patient's clinical status to evaluate whether there was significant neurological deterioration during therapy with tetrathiomolybdate. This was achieved by two separate and independent evaluations, one of speech function and one of overall neurologic function. A baseline quantitative neurological examination was performed by one of us (A.B.Y.) using methods previously described,[12] another was conducted during the midpoint of the 8-week tetrathiomolybdate treatment, and a final one was performed at the end of the 8 weeks. The results of the initial and final examinations are reported here by a scoring system previously described[12] that quantitatively evaluates tremor, dysarthria, fine-motor coordination, resting dystonia, and rigidity. Worsening is depicted by a higher score, improvement by a lower score. Clinical motor speech function was evaluated with oral motor examinations, and perceptual speech analysis was documented with audiotape recordings. A speech pathologist (K.J.K.) analyzed and rated the severity of the dysarthria during the examination and from audiotaped samples of spontaneous speech, expository speech, oral reading of the "Grandfather Passage," diadochokinetic rates, verbal and nonverbal agility scores, counting from 1 to 75, and duration of the vowel sounds "ah" and "ee." We used the deviant speech dimensions defined by Darley et al.[13] A rating scale was devised extending from 0 (unaffected) to 6 (severely affected) for the severity of dysarthria. Initial examinations were performed within 2 to 4 days following admission and prior to initiation of therapy with tetrathiomolybdate. Examinations were repeated on a weekly basis during the administration of tetrathiomolybdate. The results of the initial and final examinations are reported here.

RESULTS

The results of the studies evaluating the potency and stability of tetrathiomolybdate under various storage conditions are shown in Figs 1 and 2. It is clear that with standard bulk storage the drug is quite stable, as measured both by absorption at 467 nm (Fig 1)

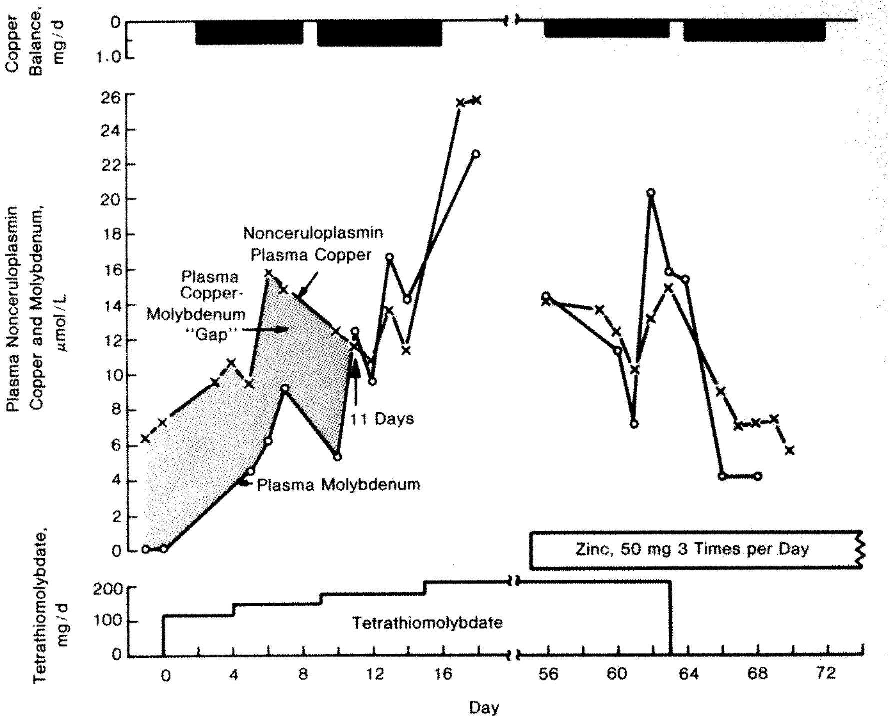

Fig 5.—Results of treatment of patient 63 with tetrathiomolybdate. This patient was discharged from the hospital for a period during the middle of the study but continued tetrathiomolybdate treatment at home.

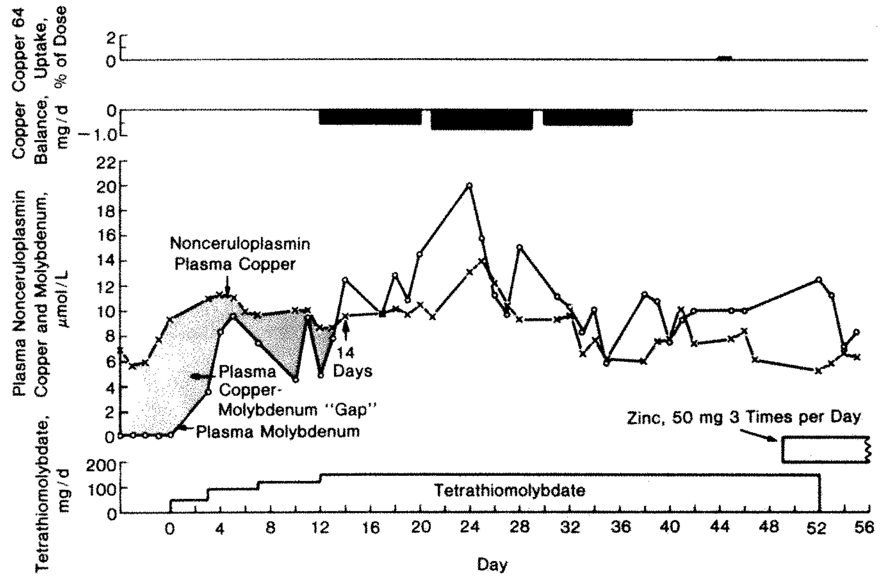

Fig 6.—Results of treatment of patient 68 with tetrathiomolybdate.

and by the amount of copper precipitated by a given concentration of tetrathiomolybdate in the bioassay (Fig 2) over the 72-week period of observation. On the other hand, exposure to air causes loss of most of the specific absorption by 31 weeks (Fig 1). However, we found that capsules stored in a pharmacy bottle at room temperature and opened repeatedly each day, as would be typical for patient use, were fully potent over an 8-week period (data not shown).

The results of the copper and molybdenum studies in the patients are shown in Figs 3 through 8. In the first patient studied (Fig 3) the initial dose was 10 mg administered three times per day with meals. This dose was escalated every 3 to 4 days until a daily dose of 150 mg (50 mg three times per day with meals) was reached. While the effect on producing a negative copper balance was immediate (Fig 3), not much effect on copper and molybdenum values was noted until the dose was divided such that half was given between meals, in a six times per day program (day 8, Fig 3). This resulted in a prompt increase in the total plasma copper level, much of which was insoluble in trichloroacetic acid (it is characteristic of tetrathiomolybdate-complexed copper to be trichloroacetic acid insoluble). The increase in the total plasma copper level was paralleled by an increase in the plasma molybdenum level. The ratio of NCPCu to molybdenum was close to unity by day 15 of therapy and thereafter (arrow, Fig 3). At no time did the patient's condition deteriorate clinically. Blockade of oral copper 64 uptake was demonstrated (Fig 3). After 6 weeks, zinc acetate therapy was added, and, after 2 weeks of concomitant therapy, tetrathiomolybdate therapy was stopped. The transition to zinc therapy was smooth. This patient has now received therapy with zinc for 2 years after initial treatment with tetrathiomolybdate and is almost fully recovered and living a normal life.

With subsequent patients (other than patient 38), the final dose was higher (Table 2), particularly on a per kilogram body-weight basis, because we wished to reach control of copper levels in the blood as quickly as possible. We also tended to shift a higher proportion of the dose to the between-meal fraction for the same reason (Table 2).

In patient 61 (Fig 4), the plasma copper-molybdenum gap was eliminated in 17 days. For unknown reasons, this patient's negative copper balance was smaller than in the other patients (Fig 4). The plasma copper-molybdenum gap was closed in 11 days in patient 63 (Fig 5) and in 14 days in patient 68 (Fig 6). Both of these latter patients showed consistent negative copper balances of about 0.5 mg/d or a little more. Patient 79 required 29 days to close the plasma copper-molybdenum gap (Fig 7). It is not clear why this patient took longer to reach this end point, although the patient did have the highest level of copper in the urine sample of the five patients receiving initial treatment (Table 1).

Patient 38 was the patient with a compliance problem with a very high initial level of copper in her urine sample (Table 1) and an NCPCu of about 7.5 µmol/L. Zinc was reinstituted as her maintenance therapy, and tetrathiomolybdate therapy was initiated as well. Her plasma copper-molybdenum gap was eliminated in 8 days (Fig 8). This patient had exhib-

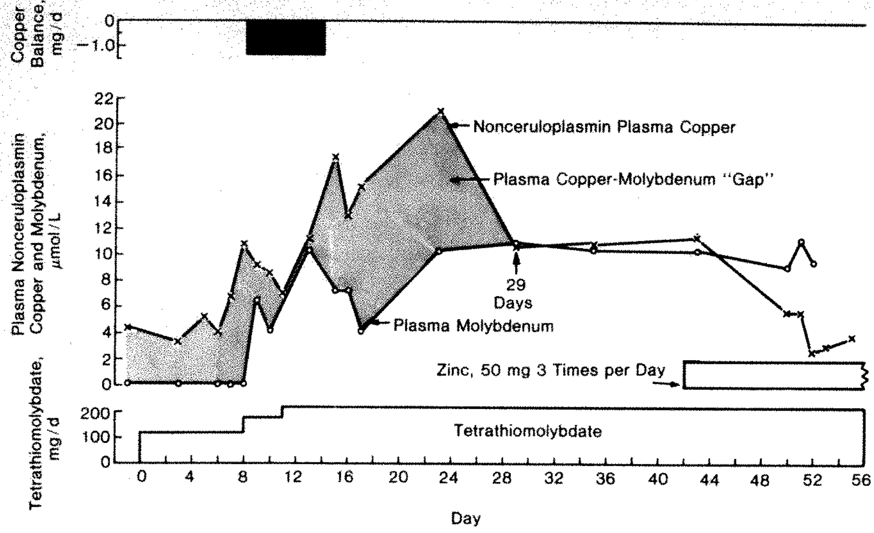

Fig 7.—Results of treatment of patient 79 with tetrathiomolybdate.

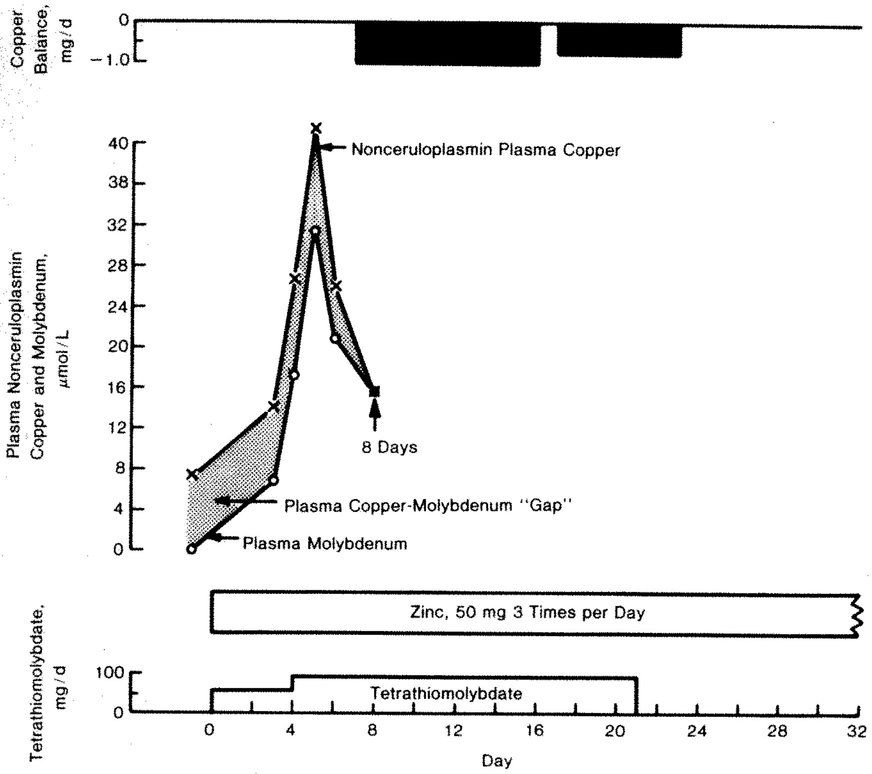

Fig 8.—As explained in the text, this patient had initially presented with neurological disease, but had long been treated with anticopper agents and was in the maintenance phase of therapy, with a stable clinical picture and mild-to-moderate neurological residual effects. She then inexplicably discontinued therapy. When admitted for a routine checkup, we found dangerously high urine, copper, and nonceruloplasmin plasma copper values and elevated liver-derived serum enzyme values. She was treated with a combination of zinc and tetrathiomolybdate, in an effort to prevent the development of new neurological symptoms.

ited liver copper toxicity in terms of elevated enzyme values, and these elevated enzyme values decreased quickly with the combined tetrathiomolybdate and zinc therapy (Table 3).

The rapid decrease in trichloroacetic acid-soluble copper in urine during the period of tetrathiomolybdate therapy in these six patients should also be noted (Table 4).

The results of the quantitative neurological and speech examinations are shown in Table 5. Patient 38 is not included because of her different status. Of the four patients scored for neurological status at the beginning and at the end of the 8-week tetrathiomolybdate treatment, two showed mild improvement and two were unchanged. Of the five patients scored for dysarthria, two showed mild improvement and three were unchanged. The most important finding is that none worsened.

A patient deserving of special comment is patient 68. This patient had the most severe brain involvement detected by magnetic resonance imaging of the brain of any of our series of 61 patients. He had involvement of white matter areas as well as basal ganglia. This patient's course was similar to the other patients in that his neurological symptoms referable to Wilson's disease did not worsen. It was different in that his recovery was much less complete and that intermittent seizures developed. We do not believe the seizures are related to therapy with tetrathiomolybdate, but they are probably due to the original brain damage. The only other patient in our series who had white matter lesions observed on magnetic resonance imaging scans also had seizures, and he had been treated only with penicillamine.

COMMENT

Two aspects of the results reported here on the first six patients treated with tetrathiomolybdate will be discussed. The first aspect is an analysis of the preliminary results related to the drug and drug regimen—drug stability, methods of storage, methods of assay, methods of administration, dose response, methods of evaluating end points of therapy in this setting, and methods of transition to maintenance anticopper agents. The second aspect relates to the therapeutic objective of quickly gaining control over copper toxicity and preventing neurological worsening.

Addressing the first aspect, we believe that we have evolved preliminary methodology that makes tetrathiomolybdate operationally quite usable. The active product is easily assayed, and we have a biological assay that confirms potency. The drug in bulk form stored under anaerobic conditions at room temperature is adequately stable. Under conditions of use by patients for 8 weeks it is also adequately stable.

The therapeutic end points of interest with respect to copper were blockade of intestinal copper absorption and neutralization of potentially toxic levels of copper. We found that these end points could be effectively evaluated by using copper balance and blockade of copper 64 absorption for the first end

Table 3.—Response of Liver-Derived Serum Enzyme Values in Patient 38

*From Young et al.[12]

†This patient's results were not scorable at the time of the neurological examination because of sedation from antiseizure medication.

point of interest, and the ratio of molybdenum to NCPCu in plasma for the second. The latter determination can be used to titrate the time point at which the NCPCu is fully occupied with tetrathiomolybdate. We found the use of trichloroacetic acid copper solubility[6,9] less reliable, particularly if the patient had had a significant amount of circulating ceruloplasmin.

It appears that to obtain both mechanisms of action a program of administering the drug both *with* (to obtain blockade of copper absorption) and *between* meals (to obtain tetrathiomolybdate absorption and neutralization of potentially toxic levels of copper) is optimal. It appears that a daily dose of 2 to 3 mg/kg of body weight, with a distribution of drug approximately one third with meals and two thirds between meals, achieves both effects. Blockade of copper absorption is immediate, while it took 8 to 29 days (mean, 16.7 days) to accomplish complete neutralization of NCPCu in plasma.

We evaluated only one type of transition to maintenance therapy, that to zinc acetate. This transition went smoothly. Based on unpublished animal studies, we also believe that a patient's therapy could be transitioned to penicillamine or trien without difficulty.

With regard to the second aspect, whether tetrathiomolybdate is superior to other agents in the initial treatment of Wilson's disease in terms of preventing worsening of neurological disease, obviously a more definitive study, possibly a side-by-side comparison, must be performed. The post hoc penicillamine study revealed that the condition of 13 of 25 patients worsened,[3] and, in the present study with tetrathiomolybdate, the condition of zero of five patients worsened (patient 38 cannot be counted because her situation was not one of initial treatment). While these results are statistically significant by χ^2 analysis ($P < .05$), they must be taken as only giving preliminary encouragement until a more definitive study is conducted. In spite of the limited number of patients studied, we believe these early results with tetrathiomolybdate are quite exciting. From the theoretical standpoint, tetrathiomolybdate has ideal properties for quickly controlling copper toxicity, and these early results so far bear out the theoretical expectation. No toxic reactions were observed from this therapy over the 8 weeks of use in these patients.

The Neural Substrate of Memory Impairment Demonstrated by the Intracarotid Amobarbital Procedure

Kimberlee J. Sass, PhD; Todd Lencz; Michael Westerveld, PhD;
Robert A. Novelly, PhD; Dennis D. Spencer, MD; Jung H. Kim, MD

• The intracarotid amobarbital sodium (Amytal) procedure (IAP) was performed for 46 patients with temporal lobe epilepsy (21 with left seizure foci; 25 with right seizure foci). After anteromedial temporal lobectomy, neuronal densities were established for hippocampal subfields CA1, CA2, and CA3; the hilum; and the dentate granule cell layer. Intracarotid amobarbital procedure memory results were related to CA3 neuronal loss only. Patients who did not demonstrate memory after injection contralateral to the seizure focus had significantly fewer cells in CA3 than patients who did. Additionally, a significant correlation was observed between the intracarotid amobarbital procedure memory examination raw score after injection contralateral to the seizure focus and CA3 cell density. Using χ^2 analysis, significant differences were documented in the frequency with which memory was demonstrated after injection contralateral to the seizure focus for groups of patients classified by degree of CA3 neuronal loss. This finding supports prior research showing subfield specificity in some memory processes.

(*Arch Neurol.* 1991;48:48-52)

The intracarotid amobarbital sodium (Amytal) procedure (IAP) originally involved only the assessment of language during unilateral anesthetization. A brief memory assessment was added to the IAP[1] as a means of avoiding the amnesic syndrome that occasionally followed unilateral temporal lobectomy with hippocampectomy.[2] Although IAP memory findings are considered by many to be a measure of hippocampal function,[3-6] few attempts have been made to demonstrate the correspondence of IAP memory findings and hippocampal damage.

Rausch et al[6] found that patients with severe neuron loss throughout the hippocampus generally failed the IAP memory examination, but results in patients with moderate neuron loss were mixed. These authors did not examine the hippocampal subfields individually. Sass et al[7] demonstrated a relationship between clinical memory impairment and neuron loss only in CA3 and the hilar area. Rausch and coworkers' use of a composite measure of neuron loss may have obscured the relationship between IAP memory performance and neuron loss in specific subfields for those patients with only moderate hippocampal damage. The present report summarizes evidence of specificity in the relationship between hippocampal neuron loss and IAP memory performance.

PATIENTS AND METHODS

Patients

Forty-six patients with medically refractory epilepsy localized to the temporal lobe (21, to the left; 25, to the right) underwent the IAP prior to surgery. Seizure onset was localized using electroencephalography of the scalp with simultaneous audiovisual recording of at least three clinical seizures. In addition, 35 patients underwent invasive electroencephalographic evaluation (12 had depth electrodes, one had subdural electrodes, and 22 had both depth and subdural electrodes implanted). Computed tomography, magnetic resonance imaging, and angiography detected no structural lesions (eg, tumors, vascular malformations, and infarcts). Mesial temporal sclerosis was not considered a structural lesion for purposes of this study.

All patients were 16 years of age or older and left hemisphere dominant for speech. Every patient had a full-scale intelligence quotient above 70, as measured by the Wechsler Adult Intelligence Scale-Revised. Patients with left seizure foci did not differ significantly from patients with right seizure foci with regard to history of febrile convulsions, age of seizure intractability, or age at surgery. This information is summarized in Table 1. Excluding seizures during the acute postoperative period and those occurring with medication changes, 40 patients were seizure free during the 6-month period following surgery. The remaining six patients (four with left foci, two with right foci) had at least an 80% reduction in seizure frequency.

IAP

Patients were seizure free for at least 12 hours before the IAP was performed. Both hemispheres were studied in all patients, and the hemisphere with the suspected lesion was always injected with amobarbital first. The period between injections was approximately 1 hour in duration. Prior to the procedure, a brief language examination was performed to detect any preexisting language disorder. This language examination assessed expository speech, comprehension, repetition, and naming.

Catheterization of the internal carotid artery was achieved via a transfemoral approach. One hundred thirty milligrams of 10% amobarbital sodium, diluted in 100 mL of saline was injected manually. The duration of the injection was approximately

4 seconds. When dense hemiplegia contralateral to the injection side was demonstrated, memory stimuli were presented visually to the patient. The stimuli were similar in design for both hemispheres. These stimuli included two line drawings of common objects, two simple words, a colored geometric form, and a simple arithmetic operation. Patients were asked to name the objects, to read the words, to identify the color and shape of the geometric form, and to recite the arithmetic problem. When the dominant hemisphere was injected, the patient could not comply with these commands, because he or she could not speak. However, the patient's attention to stimuli could be demonstrated by accurate visual tracking when the stimuli were slowly moved. Each stimulus was exposed for approximately 25 seconds, only during the period of acute anesthetization.

Identification of the memory stimuli during anesthetization constituted a portion of the language examination (ie, object naming and reading). After the memory stimuli were presented, examination of spontaneous speech, repetition, and comprehension continued. Approximately 10 minutes after the injection, if normal strength was demonstrated bilaterally and no aphasic signs were present, the patient was asked to recall the memory stimuli. For those items that were not recalled spontaneously, recognition was tested by asking the patient to select from four stimuli (one correct item and three foils) the one that had been exposed during the procedure. The patient's test score was the sum of items recalled and recognized. Ordinarily, test scores of 2 or more (ie, at least 33% correct responses) were considered to reflect intact memory. However, to approximate the procedure used elsewhere,[6] IAP memory results were also computed, with 4 points (ie, 67% correct responses) required for a passing score.

All IAP memory results presented in this report refer to performance following injection of the hemisphere contralateral to the seizure focus. In other words, the results refer to performance by the hemisphere ipsilateral to the seizure focus, where the operation would ultimately be performed. All patients demonstrated memory following injection of the hemisphere ipsilateral to the seizure focus, which is required for patients undergoing temporal lobectomy at our institution.

Surgical Procedure and Tissue Analysis

The surgical procedure and the method of tissue analysis used in this study were identical to those detailed in a previous publication.[7] For the convenience of the reader, these procedures are reviewed here as well.

All patients underwent anteromedial temporal lobectomy and radical hippocampectomy, without intraoperative cortical stimulation or electrocorticography. The anteromedial temporal lobectomy involved small neocortical resection (3 to 3.5 cm for the dominant hemisphere, 4 to 4.5 cm for the nondominant hemisphere). The cortical incision bisected the middle temporal gyrus, sparing the superior temporal gyrus.

Table 1.—Demographic Information*

The hippocampus was exposed by dissection of the occipitotemporal fasciculus. Medial structures, including the amygdala, parahippocampus, and hippocampal formation, were removed en bloc, using the operating microscope. The hippocampus was cut posteriorly at its curve around the superior colliculus.

A coronal section, 2 mm in thickness, was obtained from the midsection of the hippocampus. This was placed in 4% buffered formaldehyde solution in the operating room, and then transferred to the laboratory for further fixation, dehydration, and paraffin embedding. Four paraffin sections, 6 μm in thickness, were stained with hematoxylin-eosin, Luxol fast blue, and Nissl and/or Bodian method. However, the most successful results were obtained using hematoxylin-eosin, and the majority of cases were processed in this fashion.

Separate cell counts were obtained for CA1, CA2, CA3, the hilar area, and the granular layer of area dentata. Neuronal nuclei were counted in areas measuring 200 × 400 μm for the pyramidal cell fields and 50 × 100 μm for the granule cell area. The neuronal counts were adjusted using Abercrombie's formula (8 μm was used for the nuclear diameter of pyramidal cells; and 6 mm, for granular neurons).[8] Five separate areas were counted for each subfield, and the average for each subfield was computed. Separate counts were obtained from two observers who were blind with respect to presurgical examination findings. Neuronal densities are expressed as measures of volume (mean cell count per cubic millimeter).

Normative cell densities were established using tissue collected during autopsy of 14 adults who died of nonneurologic causes. Tissue was obtained within 8 hours post mortem.

RESULTS

Patients with epilepsy, contrasted with autopsy controls, had significant pyramidal cell loss in CA1, CA2, CA3, and the hilum of area dentata (multivariate analysis of variance results, $P < .001$). Granule cell densities within area dentata also were significantly less than those of the autopsy controls ($P < .001$). Neuron densities of patients whose seizure focus was identified by nonsurgical means (ie, electroencephalography of the scalp, neuropsychological examination, and IAP findings) did not differ significantly from those of patients who underwent depth electrode implantation or subdural electroencephalographic recording.

	Fail	Pass
Severe neuron loss	9	3
Moderate neuron loss	9	18
Normal cell counts	1	3

Table 4.—Cross Tabulation of Intracarotid Amobarbital Procedure Memory Failures and Classification of CA3 Neuron Loss (N = 43)

	Conservative Scoring Criterion	
	Fail	Pass
Severe neuron loss	12	0
Moderate neuron loss	19	8
Normal cell counts	1	3

The mean number of items recalled by patients with left temporal seizure foci following perfusion of the right hemisphere was 2.29 items (SD, 2.22 items). Patients with right temporal seizure foci recalled an average of 1.96 items (SD, 2.01 items) following perfusion of the left hemisphere. The group difference was not statistically significant; therefore, lateralization of the seizure foci was not considered in subsequent analyses.

Patients were classified by their success or failure in demonstrating memory within the hemisphere in which surgery would ultimately be performed. Using our standard scoring criterion (pass, 2 or more points), 25 patients demonstrated memory following injection contralateral to the planned surgery site (ie, a pass) and 21 did not (ie, a failure). Using the alternative scoring criterion (pass, 4 or more points), 11 patients passed and 35 failed.

Patients who failed the IAP memory examination had significantly fewer neurons in CA3 ($P < .01$) than patients who passed the examination, regardless of the scoring criterion (eg, 2 points or 4 points). Pearson product moment correlations documented a statistically significant correlation between IAP memory examination raw scores (range, 0 to 6) and CA3 volumetric cell density ($r = .38$; $P < .01$) (Table 2). No other statistically significant correlations or group differences were observed for any other hippocampal subfield.

Patients were divided into three groups using methodology similar to that of Rausch et al.[6] Rausch and colleagues separated patients with less than 20% of the mean volumetric neuron measurement of the autopsy controls from those patients with less severe neuron loss. Patients in the present sample who had severe hippocampal neuron loss also were separated from the others. The classification was based only on the number of neurons in CA3, the only field in which neuron counts were related to IAP memory performance. The autopsy controls in Rausch and coworkers' study had a mean volumetric neuron density of 21773 in CA3. Rausch et al[6] and Babb et al[9] used the same normal controls. Rausch and associates established a criterion for the classification of severe neuron loss (80% the number of cells in autopsy controls reported by Babb and colleagues). However, they did not establish a normal range. For consistency in classification of patients with severe neuron loss, we used the same criterion that they did. In the absence of any standard proposed by Rausch and coworkers, we established a normal range using our own autopsy controls. Patients in our sample whose volumetric neuron density was less than 4354.6 for CA3 (20% of 21773) were classified as having severe neuron loss (n = 12).

Rausch et al[6] considered all other patients (ie, those with less than 80% neuron loss) to have moderate neuron loss. Inspection of our data indicated that some patients had minimal or no neuron loss. Therefore, a third group was identified. Patients whose neuron counts were within two standard deviations of mean volumetric neuron density observed for our autopsy control sample were classified as having normal neuron counts (n = 4). All others were classified as having moderate neuron loss (n = 27). The tissue samples for three patients were not suitable for establishing the volumetric cell density of CA3. Therefore, only 43 of 46 patients were classified according to CA3 neuron loss.

The IAP memory findings (pass or fail) for the side that was operated on were cross tabulated with neuron density classifications (ie, severe neuron loss, moderate neuron loss, and normal). These cross tabulations are shown in Tables 3 (pass, 2 items or more) and 4 (pass, 4 items or more). Failures during the IAP memory examination were increasingly more frequent with greater neuron loss. The χ^2 analysis was statistically significant, regardless of the scoring criterion ($P < .05$).

COMMENT

In 1958, Penfield and Milner[10] reported two cases of persistent anterograde amnesia following unilateral temporal lobectomy with hippocampectomy. These two cases of amnesia were quantitatively similar to the syndrome observed following bilateral hippocampectomy,[11] so Penfield and Milner suspected the presence of a lesion in the temporal lobe contralateral to the surgical procedure. Hippocampal injury contralateral to the surgical excision was ultimately demonstrated at autopsy.[10] Later, Milner et al[1] reported "a severe and lasting memory disturbance" following unilateral temporal lobectomy with hippocampectomy in three of 18 patients with bilateral electroencephalographic or radiological evidence of damage to the temporal lobes.

Milner et al[1] proposed that severe postoperative memory impairments following unilateral temporal lobectomy with hippocampectomy could be avoided by a technique that accurately assessed the integrity of each hippocampal formation. At the time, the IAP was becoming accepted as a reliable technique for determining speech lateralization. Milner and coworkers hypothesized that when the hemisphere that had been selected for surgery was temporarily anesthetized with amobarbital sodium, memory examination would identify "a lesion involving the hippocampal zone of the opposite hemisphere." Consequently, they added a brief memory assessment to the IAP.

Initially, Milner et al[1] encountered failures on the IAP memory test only after injection contralateral to the side of the proposed surgery (ie, when the side of the suspected lesion was examined). These cases posed no risk for postoperative amnesia, because adequate memory function was present in the contralateral hemisphere. Later, Milner[3] encountered memory impairments after injection of the hemisphere ipsilateral to the proposed surgery. When this result was obtained the patient was not denied surgery Instead, the surgical procedure fo these patients was modified to spar the hippocampus and parahippocam pal gyrus, based on the belief that IA memory failure indicated a damage hippocampus contralateral to the injection side.[3,5] Milner[3] reported thre cases in which a patient, having faile to demonstrate adequate memory o the side contralateral to the propose surgery, underwent temporal lobectomy in which the hippocampus wa spared. None of the patients involve became amnesic.

In the years since its development the IAP memory examination has become a routine component of the presurgical evaluation of patients wit medically refractory epilepsy.[11] Lik Milner,[1,3] many researchers believe th IAP is a measure of medial tempora lobe or, specifically, of hippocampa function. This interpretation is sometimes stated explicitly.[1-3,6] In other reports, the connection between IA memory performance and hippocampal functioning can be inferred fro the practice of preserving the hippocampus during surgery for patients who failed to demonstrate memory contralateral to the surgical site (ie when the ipsilateral hemisphere was perfused).[12]

Several studies have shown that the likelihood of IAP memory failure is greater when the hemisphere contralateral to the seizure focus is perfused.[1,6,13,14] However, there has been little direct evidence that the IAP is sensitive to the degree of hippocampal damage.

Rausch et al[6] examined the memory of 30 patients during the IAP. Quantified pyramidal cell counts for the subfields of the hippocampus and the prosubiculum were obtained for 29 of the 30 patients following unilateral temporal lobectomy and hippocampectomy. Neuron densities were established for anterior and posterior planes, the latter defined as 3 cm from the anterior aspect of the hippocampus. Four of five patients with severe hippocampal damage, operationally defined as more than 80% neuron loss, failed to demonstrate memory from the hemisphere selected for surgery (ie, following perfusion of the hemisphere contralateral to the seizure focus). In contrast, only 58% of patients with moderate neuron loss failed to demonstrate memory during the IAP. Rausch et al[6] noted that, "Several patients with minimal hippocampal damage failed IAP memory testing on contralateral injection, while patients with more marked damage passed the IAP memory component." The authors concluded that IAP memory failure in patients with severe hippocampal damage was the result of the neuron loss. They suggested that IAP memory failures by patients with moderate neuron loss could have involved recent seizure phenomena or interictal epileptiform activity. Nevertheless, they regard all IAP memory failures as "indicative of significant surgical risk to global memory."

The present study was designed to further examine the sensitivity of the IAP memory examination to hippocampal neuron loss. Rausch and colleagues'[6] measure of hippocampal neuron loss was a composite of five fields. A previous report of the relationship between hippocampal neuron loss and clinical memory indicated that only neuron loss in CA3 and the hilum correlated with memory impairment.[7] The present study was designed to determine whether hippocampal subfield specificity exists with respect to the IAP memory findings.

Patient selection criteria for the present study were virtually identical to those of Rausch et al.[6] In both samples, localization of seizure onset rather than interictal spiking was the criterion for surgical planning. A comparable number of patients in each study were selected by depth electrode implantation, subdural recordings, and surface recording only. The patients were approximately the same age when habitual seizures began and at surgery. The rate of failures on the IAP memory examination was similar. Rausch and associates reported failures in 19 (66%) of 29 patients. Using their scoring criterion, we observed memory failures in a comparable number of patients (35 [76%] of 46). Surgical techniques were similar, except that the procedure described herein resulted in a more radical excision of the hippocampus. Even so, the section obtained for analysis in this study corresponded to the posterior section obtained by Rausch et al.[6]

In the present sample, IAP memory results were related to neuron loss only in CA3. This relationship was demonstrated in three ways. Patients failing the IAP had significantly fewer neurons in CA3 than patients who had passed, regardless of the scoring criterion (eg, 2 or 4 items required for a passing score). A significant correlation was observed between IAP memory examination raw score and CA3 neuron density. χ^2 Analyses documented differences in the frequency of IAP memory failures, regardless of scoring criterion, in groups of patients classified according to the degree of neuron loss in CA3.

By classifying patients only according to neuron loss in CA3, we identified a greater number of patients with severe neuron loss (12 [28%] of 43). Only five (17%) of 29 patients in the study of Rausch et al[6] were classified as having severe neuron loss using the composite index. Patients with severe neuron loss could reasonably have been expected to fail the IAP memory examination. Four of the five patients in Rausch and coworkers' sample and all 12 of the patients in our sample did so (using Rausch and coworkers' scoring criterion). By classifying patients only by neuron loss in CA3, we also identified four patients (9%) with normal cell counts. These four patients could reasonably have been expected to pass the IAP memory examination, and three of them did. Altogether, classifying patients only on the basis of neuron loss in CA3 allowed us to make reasonable predictions regarding IAP memory performance for 37% of our sample (16 of 43 patients), and 94% of these (15 of 16) performed as expected. In contrast, Rausch and colleagues' classification system identified only 17% of the sample about whom reasonable predictions could be made, and only 80% of these performed as expected.

The findings of the present study and the contrast of this study with that of Rausch et al[6] suggest that specificity with regard to subfield exists in the relationship of IAP memory performance and hippocampal neuron loss. This finding is consistent with that of a prior study showing similar specificity in the relationship of clinical memory (eg, list learning) and hippocampal neuron loss.[7] Sass et al[7] reported that performance on the verbal Selective Reminding Test correlated only with CA3 and hilar neuron loss in patients with left temporal seizure foci.

Like Rausch et al,[6] we observed mixed results in patients with moderate neuron loss. Rausch and associates reported that 14 (58%) of 24 patients with moderate neuron loss failed to demonstrate memory during the IAP. Several explanations for these failures were offered. These included recent seizure phenomena or interictal epileptiform activity; the role of the hippocampal lesion was minimized. Rausch and coworkers appeared to interpret IAP memory failures in the moderate neuron loss group as false-positive errors (with respect to documenting severe neuron loss). Using their scoring criterion, 19 (70%) of 27 patients in our sample with moderate neuron loss in CA3 failed the IAP memory examination. We believe the hippocampal lesion was central to these failures. Therefore, we are inclined to interpret adequate demonstration of memory during the IAP by patients with moderate neuron loss as false-negative errors (with respect to documenting the neuron loss in CA3).

There can be several reasons why moderate neuron loss in CA3 may be associated with intact memory during the IAP. Rausch et al[6] reported a relationship between perfusion of the posterior circulation and IAP failure for a portion of their sample (ie, those with severe neuron loss). The cerebral vasculature also varies with regard to filling of the anterior cerebral distribution from a middle cerebral injection. The reappearance of contralateral motor function or speech is used as an index of hemispheric recovery from anesthetization. Variance in vascular distribution of the frontal areas, as well as variance in the threshold for anesthetization and rate of recovery of frontal vs medial temporal areas, may lead to participation of the injected hemisphere in the mnemonic process, despite the presence of contralateral hemiplegia or mutism/dysphasia. Finally, recognition memory is tested in a multiple choice format. With a ratio of 3:1 (foils to targets), chance responding would yield an average score of 1.67 correct. The possibility that some patients correctly guessed one or more stimuli must be considered. We minimize this by scoring items as correct only if the patient reports a clear recognition of the item (ie, he or she is not guessing). However, it is impossible to control completely for guessing.

The overwhelming majority of patients in our sample failed to demonstrate memory from the side of seizure focus (ie, after perfusion of the hemisphere contralateral to the seizure focus) during the IAP memory examination (using the scoring criterion of Rausch et al[6]). All but one of the patients who failed the IAP memory examination had moderate or severe neuron loss in CA3. Furthermore, a significant relationship between moderate or severe neuron loss in CA3 and clinical memory has also been demonstrated.[7] The results of the present study indicate that failure to demonstrate memory following anesthetization of the hemisphere that will be operated on identifies patients at risk for significant postoperative memory impairments. These data support the practice of denying surgery to patients who fail to demonstrate memory during the IAP from the hemisphere that will remain intact after the planned surgery.

These findings and those of Sass et al[7] demonstrate a relationship between damage in CA3 and some types of memory impairments. Although noting this correlation, we do not ascribe to CA3 a special role with regard to some specific aspect of memory. Neuroanatomical studies have shown CA3 to be part of a neural network that includes CA1 and the subiculum.[15-17] Zola-Morgan et al[18] reported memory impairments in a patient with bilateral CA1 lesions. Jarrard et al[19,20] reported that damage to the subiculum had a causative role with regard to some memory impairments in animals. Although it is premature to specify the manner in which damage to any of these areas affects memory, we believe there is ample evidence to suggest that hippocampal subfield specificity exists with regard to cognitive functions.[17] We encourage future researchers to further investigate hippocampal subfield specificity, rather than to assume that the hippocampus functions as a single unit.

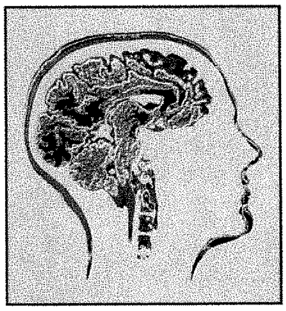
THROUGH A CALCIUM-MODULATING MECHANISM OF ACTION



CEREBROSELECTIVE

NIMOTOP®

nimodipine/Miles

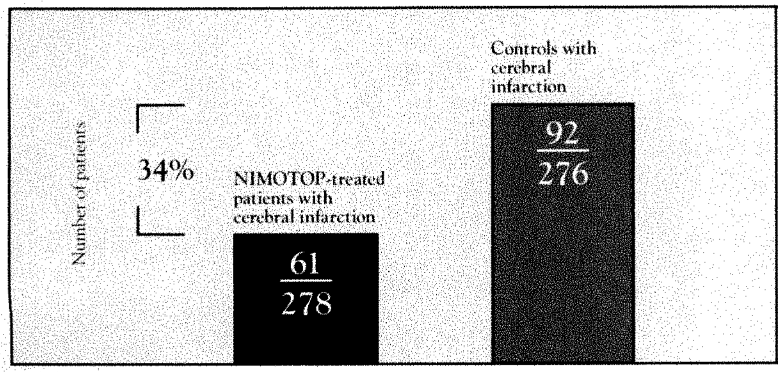
CAPSULES 30 mg

REDUCES INCIDENCE OF CEREBRAL INFARCTION IN PATIENTS FOLLOWING SUBARACHNOID HEMORRHAGE

In the largest study to date, NIMOTOP demonstrated a significant reduction in incidence of cerebral infarction[1]

- Twenty-two percent (61/278) of NIMOTOP-treated patients experienced cerebral infarction vs. 33% (92/276) of controls
- NIMOTOP reduced the incidence of cerebral infarction by 34%

Thirty-four percent reduction in incidence of cerebral infarction with NIMOTOP-treated patients vs. controls (n=554; p=0.003)[1]*



*90% of patients in this study were Hunt and Hess Grades I-III.

Dose: 60 mg (two 30 mg liquid-filled capsules) every 4 hours for 21 days commencing within 96 hours of SAH.

Adapted from Pickard, et al.[1]

NIMOTOP modulates calcium influx to promote cerebral perfusion, and may directly protect neurons[2-5]

"[In animals] The beneficial cytoprotective effect of nimodipine, probably related to normalization of calcium homeostasis and blood-brain barrier permeability after ischemia, may reflect both vascular and cellular sites of action."[6]

Lazarewicz JW, et al. *Stroke* 1989.

"[In humans] The data thus suggest that nimodipine neither prevents nor reverses cerebral vasospasm. Calcium channel blockers such as nimodipine may have an effect on cerebral arterioles that are below the limits of resolution of angiography. . . ."[1]

Pickard JD, et al. *Br Med J* 1989.

MILES

CEREBROSELECTIVE

NIMOTOP®

nimodipine/Miles

CAPSULES 30 mg

NIMOTOP REDUCES THE INCIDENCE OF CEREBRAL INFARCTION FOLLOWING SUBARACHNOID HEMORRHAGE

BRIEF SUMMARY
NIMOTOP® (nimodipine/Miles) CAPSULES
For Oral Use

INDICATIONS AND USAGE

Nimotop® (nimodipine) is indicated for the improvement of neurological deficits due to spasm following subarachnoid hemorrhage from ruptured congenital intracranial aneurysms in patients who are in good neurological condition post-ictus (e.g. Hunt and Hess Grades I-III). Oral Nimotop® therapy should begin within 96 hours of the subarachnoid hemorrhage and continue for 21 days.

CONTRAINDICATIONS

None known.

PRECAUTIONS

General: Blood Pressure: Nimodipine has the hemodynamic effects expected of a calcium channel blocker, although they are generally not marked. In patients with subarachnoid hemorrhage given Nimotop® in clinical studies, about 5% were reported to have had lowering of the blood pressure and about 1% left the study because of this (not all could be attributed to nimodipine). Nevertheless, blood pressure should be carefully monitored during treatment with Nimotop® based on its known pharmacology and the known effects of calcium channel blockers.

Hepatic Disease: The metabolism of Nimotop® is decreased in patients with impaired hepatic function. Such patients should have their blood pressure and pulse rate monitored closely and should be given a lower dose (see Dosage and Administration).

Laboratory Test Interactions: None known.

Drug Interaction: It is possible that the cardiovascular action of other calcium channel blockers could be enhanced by the addition of Nimotop®.

In Europe, Nimotop® was observed to occasionally intensify the effect of antihypertensive compounds taken concomitantly by patients suffering from hypertension: this phenomenon was not observed in North American clinical trials.

Carcinogenesis, Mutagenesis, Impairment of Fertility: In a two-year study, higher incidences of adenocarcinoma of the uterus and Leydig-cell adenoma of the testes were observed in rats given a diet containing 1800 ppm nimodipine (equivalent to 91 to 121 mg/kg/day nimodipine) than in placebo controls. The differences were not statistically significant; however, the higher rates were well within historical control range for these tumors in the Wistar strain. Nimodipine was found not to be carcinogenic in a 91-week mouse study but the high dose of 1800 ppm nimodipine-in-feed (546 to 774 mg/kg/day) shortened the life expectancy of the animals. Mutagenic studies, including the Ames, micronucleus and dominant lethal tests were negative.

Nimodipine did not impair the fertility and general reproductive performance of male and female Wistar rats following oral doses of up to 30 mg/kg/day when administered daily for more than 10 weeks in the males and 3 weeks in the females prior to mating and continued to day 7 of pregnancy. This dose in a rat is about 4 times the equivalent clinical dose of 60 mg q4h in a 50 kg patient.

Pregnancy: Pregnancy Category C. Nimodipine has been shown to have a teratogenic effect in Himalayan rabbits. Incidences of malformations and stunted fetuses were increased at oral (by gavage) doses of 1 and 10 mg/kg/day administered from day 6 through day 18 of pregnancy but not at 3.0 mg/kg/day in one of two identical rabbit studies. In the second study an increased incidence of stunted fetuses was seen at 1.0 mg/kg/day but not at higher doses. Nimodipine was embryotoxic, causing resorption and stunted growth of fetuses, in Long Evans rats at 100 mg/kg/day administered by gavage from day 6 through day 15 of pregnancy. In two other rat studies, doses of 30 mg/kg/day nimodipine administered by gavage from day 16 of gestation and continued until sacrifice (day 20 of pregnancy or day 21 post partum) were associated with higher incidences of skeletal variation, stunted fetuses and stillbirths but no malformations. There are no adequate and well controlled studies in pregnant women to directly assess the effect on human fetuses. Nimodipine should be used during pregnancy only if the potential benefit justifies the potential risk to the fetus.

Nursing Mothers: Nimodipine and/or its metabolites have been shown to appear in rat milk at concentrations much higher than in maternal plasma. It is not known whether the drug is excreted in human milk. Because many drugs are excreted in human milk, nursing mothers are advised not to breast feed their babies when taking the drug.

Pediatric Use: Safety and effectiveness in children have not been established.

ADVERSE REACTIONS

Adverse experiences were reported by 92 of 823 patients with subarachnoid hemorrhage (11.2%) who were given nimodipine. The most frequently reported adverse experience was decreased blood pressure in 4.4% of these patients. Twenty-nine of 479 (6.1%) placebo treated patients also reported adverse experiences. The events reported with a frequency greater than 1% are displayed below by dose.

EKG Abnormalities	0	1 (1.4)	0	1 (0.6)	0	0
Tachycardia	0	1 (1.4)	0	0	0	0
Bradycardia	0	0	5 (1.0)	1 (0.6)	0	0
Muscle Pain/Cramp	0	1 (1.4)	1 (0.2)	1 (0.6)	0	0
Acne	0	1 (1.4)	0	0	0	0
Depression	0	1 (1.4)	0	0	0	0

There were no other adverse experiences reported by the patients who were given 0.35 mg/k q4h, 30 mg q4h or 120 mg q4h. Adverse experiences with an incidence rate of less than 1% in the 60 mg q4h dose group were: hepatitis; itching; gastrointestinal hemorrhage; thrombocytopenia anemia; palpitations; vomiting; flushing; diaphoresis; wheezing; phenytoin toxicity; lightheadedness; dizziness; rebound vasospasm; jaundice; hypertension; hematoma.

Adverse experiences with an incidence rate less than 1% in the 90 mg q4h dose group were itching; gastrointestinal hemorrhage; thrombocytopenia; neurological deterioration; vomiting diaphoresis; congestive heart failure; hyponatremia; decreasing platelet count; disseminated intravascular coagulation; deep vein thrombosis.

As can be seen from the table, side effects that appear related to nimodipine use based on increased incidence with higher dose or a higher rate compared to placebo control, included decreased blood pressure, edema and headaches which are known pharmacologic actions o calcium channel blockers. It must be noted, however, that SAH is frequently accompanied b alterations in consciousness which lead to an under reporting of adverse experiences. Patient who received nimodipine in clinical trials for other indications reported flushing (2.1%) headache (4.1%) and fluid retention (0.3%), typical responses to calcium channel blockers. As a calcium channel blocker, nimodipine may have the potential to exacerbate heart failure in susceptible patients or to interfere with A-V conduction, but these events were not observed.

No clinically significant effects on hematologic factors, renal or hepatic function or carbohydrate metabolism have been causally associated with oral nimodipine. Isolated cases of non-fasting elevated serum glucose levels (0.8%), elevated LDH levels (0.4%), decreased platelet count (0.3%), elevated alkaline phosphatase levels (0.2%) and elevated SGPT levels (0.2%) have been reported rarely.

OVERDOSAGE

There have been no reports of overdosage from the oral administration of Nimotop®. Symptoms of overdosage would be expected to be related to cardiovascular effects such as excessive peripheral vasodilation with marked systemic hypotension. Clinically significant hypotension due to Nimotop® overdosage may require active cardiovascular support. Norepinephrine or dopamine may be helpful in restoring blood pressure. Since Nimotop® is highly protein-bound, dialysis is not likely to be of benefit.

DOSAGE AND ADMINISTRATION

Nimotop® is given orally in the form of ivory colored, soft gelatin 30 mg capsules for subarachnoid hemorrhage.

The oral dose is 60 mg (two 30 mg capsules) every 4 hours for 21 consecutive days. Ora Nimotop® therapy should commence within 96 hours of the subarachnoid hemorrhage.

If the capsule cannot be swallowed, e.g., at the time of surgery, or if the patient is unconscious, a hole should be made in both ends of the capsule with an 18 gauge needle, and the contents of the capsule extracted into a syringe. The contents should then be emptied into the patient's *in situ* naso-gastric tube and washed down the tube with 30 mL of normal saline (0.9%).

Patients with hepatic failure have substantially reduced clearance and approximately doubled C_{max}. Dosage should be reduced to 30 mg every 4 hours, with close monitoring of blood pressure and heart rate.

Dominant-Side Intracarotid Amobarbital Spares Comprehension of Word Meaning

John Hart, Jr, MD; Ronald P. Lesser, MD; Robert S. Fisher, MD, PhD; Pamela Schwerdt;
R. Nicholas Bryan, MD, PhD; Barry Gordon, MD, PhD

• Abolition of speech production after intracarotid amobarbital injection is generally considered evidence for language laterality. However, complex auditory comprehension may be preserved after injection of the dominant (left) side. The possibility that this sparing may be due to the intracarotid amobarbital injection not adequately deactivating some of the areas responsible for speech comprehension in the posterior part of the hemisphere was tested with a task known to be critically dependent on the left posterotemporal-inferoparietal region, one assessing visuoverbal semantic relatedness. Even when the intracarotid injection of the left side produced marked deficits of speech production, comprehension of semantic relations was still intact in eight of 15 patients. Ten of these 15 patients also received right carotid injections, none of which affected comprehension of semantic relatedness. These data indicate that the intracarotid amobarbital injection cannot always specify the laterality of all language functions, an important concern when considering surgical procedures in the dominant posterotemporal-inferoparietal region.

(*Arch Neurol.* 1991;48:55-58)

The intracarotid amobarbital test has been used extensively as one probe of cerebral lateralization of language and memory.[1-6] Its use for this purpose is based on three assumptions. The first is that amobarbital in sufficient quantity will functionally deactivate the regions through which it flows. The second is that carotid injection of amobarbital can reach all brain areas of one hemisphere that are involved in language. The third is that there is no substitution for these language functions by either ipsilateral or contralateral hemispheric regions, at least over the short interval of the test.

These assumptions may not all be correct, as some results obtained with this technique have been difficult to reconcile with other results obtained similarly. For example, left (dominant) intracarotid amobarbital injection will suppress speech production[2] and impair comprehension of commands to point to simple shapes,[7] yet spare comprehension of commands to move body parts.[2] Such findings suggest that language impairment during Wada[1] testing cannot be viewed as an all-or-nothing phenomenon.

We propose that some important language comprehension functions of the left hemisphere may not be affected by left intracarotid amobarbital injection, in particular, those critically dependent on the left posterotemporal-inferoparietal region.[8,9] To test this hypothesis, we studied performance on a task known to be specifically sensitive to damage in these regions, the ability to comprehend the semantic relatedness between a picture and a word,[9] and compared performance on this task with the ability to name and read orally the individual items during the interval of amobarbital action.

PATIENTS AND METHODS

Patients

Data from 15 patients were selected from those of 22 consecutive patients studied during a 10-month interval. All examinations were performed as part of the clinical examination of medically intractable epilepsy. All patients gave informed consent after the nature of the procedure was fully explained. The 15 patients selected for this study met the following criteria: (1) normal language and neuropsychologic abilities on baseline clinical testing, (2) either left-sided or bilateral injections, (3) absence of significant cross-over of dye to the contralateral hemisphere during the angiogram, and (4) completion of the clinical protocol to be described. Patient profiles are summarized in Table 1.

Procedures

For the intracarotid amobarbital injection, the internal carotid artery was catheterized transfemorally. Digital subtraction angiography or cut-film angiography was then performed, using pressure injection. Following the angiogram, a 5F catheter was positioned under fluoroscopic guidance in the internal carotid artery at the level of the C-2 vertebra. Amobarbital (125 mg in 1 mL of warmed sterile water) was given through the catheter by hand injection over the course of 2 to 3 seconds, as previously described.[2-6,10] The patient's clinical status was monitored with strength testing of the arms intermittently and with continuous 10-channel electroencephalogram (EEG) recording, using a modified longitudinal bipolar montage (except for one patient who had a transverse montage). The derivation used was the following: F_{p1}-F_7, F_7-T_3, T_3-T_5, $F_{p2}F_8$, F_8-T_4, T_4-T_6, F_3-C_3, C_3-P_3, F_4-C_4, and C_4-P_4.

Language and memory testing was begun using a standard protocol when adequate hemispheric deactivation was attained unilaterally, as determined by flaccid paralysis contralaterally and anterior EEG slowing ipsilaterally, and after resolution of any initial period of inattention or confusion. First, six objects were presented visually for naming and remembering,[6] followed by two words for reading, two pictures for naming, the picture-word association task to be described, and further tasks of language and visuospatial function (including oral reading of concrete and abstract words, category membership, property judgment, relative distance discrimination, and imagery tasks). When tested on the picture-word association task, all patients

†Patient with crossed language dominance.

‡Overall, performance on the semantic relatedness task was significantly greater than chance ($P < .001$, binomial test).

had, at most, 3/5 strength of the contralateral arm (weak movement against gravity), and all had slowing on the EEG ipsilaterally.

The picture-word association task consisted of a picture (top) and a word (bottom) on a sheet of paper (21.25 × 27.5 cm [8½ × 11 in]). There were four trials, two with semantically associated picture-word pairs (eg, *bed* [picture] and *sleep* [word]), and two with unrelated pairs (eg, *bus* [picture] and *scale* [word]). The patient's task was to name the picture, read the word, and then decide if the two items were related by category or function (semantic-relatedness task). The patients had been trained on these tasks in pretesting, and their training was reinforced by auditory prompting during the test ("Do these go together?" "Are these related?"). Patients responded either orally (yes or no), by nodding or shaking their head, or by performing hand gestures (on which they had been trained previously). Naming the pictures and reading the words used in the task was performed at the same time as semantic relatedness.

All tasks were pretested the day prior to the procedure using stimuli different from those used during the actual test. This pretesting familiarized patients with the procedures and established their baseline levels of performance. Also, patients were warned what to expect in terms of paralysis, disorientation, and inability to speak but not about specific deficits.

RESULTS

For all of the language tests in our standard protocol, all of the patients performed perfectly on pretesting. Performance on language tests (other than the semantic-relatedness task) during the critical phase of the injection clearly distinguished three groups (Table 1): 12 of 15 patients with impaired language during injection of the left side, interpreted as showing left-sided language dominance; two of 15 patients showing language impairment with injection of either carotid artery, interpreted as mixed dominance; and one of 15 patients showing impairment with injection of the right side only, interpreted as right-sided language dominance.

On semantic relatedness, all patients performed perfectly (four of four correct) during pretesting. Therefore, any score less than 100% correct during the injection was considered impaired. Striking dissociations in performance between speech production (naming and reading) and comprehension of the semantic relatedness of the stimulus pairs were noted (Table 2). After injection of amobarbital into the left internal carotid artery 14 of 15 patients had marked impairment on both oral word reading and picture naming, yet 8 (53%) of 15 patients could still determine whether or not the items were related by category or function (Table 2). This percentage is even greater (58%) if the four patients who were left-handed or showed crossed or mixed dominance are excluded.

After injection of amobarbital into the right internal carotid artery, however, semantic relatedness was intact for all patients (Table 3), including the patients with crossed or mixed dominance (patient 8, crossed, and patients 12 and 15, mixed).

We also examined two other possible indexes of amobarbital perfusion of the posterotemporal-inferoparietal region, ie, the arteriographic findings and the EEG. The arteriograms were reviewed by a neuroradiologist (R.N.B.) blinded to the identity of the patients and the results of the study, examining for pattern of vessels and degree of opacification of the posterior cerebral artery. In no patient did the posterior cerebral artery have a direct origin from the anterior circulation. No correlation between the degree of opacification and the pattern of performance was found.

The EEG data were also examined. These data were available in all but three patients (patient 15 had a transverse montage that did not include the T_5 or T_6 electrodes, the data from patient 6 was uninterpretable because of movement artifact, and the data

†Patient with crossed language dominance.

from patient 4's EEG were unavailable). As a measure of the perfusion of amobarbital in the posterotemporal-inferoparietal region, the degree of slowing seen in the T_3-T_5 electrode pair (left anterior temporal to posterior temporal sites) was compared with that seen in the left F_7-T_3 pair (left inferior frontal to anterior temporal sites), along with similar comparisons of the activity on the right side. In all patients but patient 14, slowing was greater anteriorly than posteriorly; in patient 14, the degree of slowing seen in the two derivations was equal. Therefore, for all subjects except patient 14 the degree of slowing posteriorly was less than the degree of slowing anteriorly, with no correlation with performance on the semantic-relatedness task.

Whether subjects could perform the semantic-relatedness task was not significantly related to age ($t = 1.4$, $P = .18$). However, subjects who failed the task did have a significantly shorter duration of seizures than did those who passed the test (6.4 years vs 18.2 years, respectively) ($t = 2.59$, $P = .03$). Also, those who failed the test were much more likely to have had a visible lesion on either side than did those who did not fail (six vs one, significant by both χ^2 and sign tests, $P \leq .01$). Time of testing following the amobarbital injection did not show a significant difference in the performance of the semantic-relatedness task for the left hemisphere injections (for intact vs impaired performance, $t = -.23$, $df = 13$, $P = .82$). The semantic-relatedness task after right hemisphere injection was performed earlier, on the average, than were the semantic-relatedness tasks after left hemisphere injection ($t = -2.44$, $df = 23$, $P = .02$). Despite this earlier testing, during a time of, presumably, greater effect from the amobarbital injections, no deficit was found on the semantic-relatedness task after the right hemisphere injections, as noted earlier.

COMMENT

Patients who received left hemisphere amobarbital injections were generally severely impaired in their ability to read aloud or name pictures after receiving the injection, except for the patient with crossed dominance. Despite these language impairments, our critical finding was that 53% of these patients were, nevertheless, able to match perfectly the same visually presented words to their corresponding pictures by their meanings or associations. If the four patients who were left-handed or showed crossed or mixed dominance on amobarbital testing are excluded, the percentage is even greater (58%). We suggest that the most parsimonious explanation of this sparing is that, even though the left posterotemporal-inferoparietal region is critical for this ability, this region may not be sufficiently affected by intracarotid amobarbital infusion in those individuals with spared performance.

Previous work has established that correct performance on the semantic-relatedness task is critically dependent on the integrity of the posterotemporal-inferoparietal region, but only in the left (dominant) hemisphere.[8,9] Right hemisphere lesions do not cause semantic errors on picture-word matching,[11] although other semantic functions are influenced by the right hemisphere.[12,13]

Individual variability in vascular supply is well recognized. It appears that the posterotemporal-inferoparietal region is variably nourished by both the middle cerebral artery and the posterior cerebral artery,[14,15] with a watershed area supplied by both.[16] Patients with infarcts in this watershed region typically present with poor comprehension with frequent semantic paraphasias, yet display otherwise fluent speech production.[17] Since the watershed region of infarction typically involves the posterotemporal region, the implication for amobarbital testing is that portions of the posterotemporal region are not principally supplied through the carotid system. Moreover, the portions that are supplied through the carotid system may be subject to dilution and rapid washout, conceivably by the vertebrobasilar system.[18] Therefore, individual variations in vascular supply and, perhaps, in cerebral representation of language,[19-21] seem sufficient to account for the observed individual variations in susceptibility to impairment on semantic relatedness by intracarotid amobarbital injection.

This hypothesized difference in perfusion could not be appreciated with either the arteriographic or EEG techniques used. These techniques, it should be emphasized, may not have been optimal for addressing this question. The arteriographic investigations used pressure injection, while the amobarbital investigations used hand injection. The EEG montage did not cover all regions of possible importance.

Another explanation of these data is possible, although it is one that we think is less likely: the language abilities necessary for the semantic-relatedness task had, somehow, shifted elsewhere in the left hemisphere, or even to the right hemisphere, in those patients who were able to accomplish the task. The cause of this shift would have been the effects of their longer seizure histories or, perhaps, whatever underlying condition led to their seizure disorders, in the absence of a visible-mass lesion. While shifts in intrahemispheric language organization have been demonstrated in patients with chronic epilepsy,[20-22] these shifts almost never occur except with lesions encroaching on the primary speech areas.[22] None of the eight patients who passed our semantic-relatedness test had such lesions. In one patient of this group (patient 1) who had a lesion visible on computed tomographic and magnetic resonance imaging scans, the lesion was in the middle portion of the superotemporal gyrus, outside of the primary speech area as shown by extraoperative direct cortical electrical stimulation[23] and excisional surgery.

It is even less likely that our data are due to a displacement of language functions to the opposite hemisphere. None of the eight patients who passed the semantic-relatedness task after amobarbital injection into the left carotid artery had the lesions that have been associated with such a shift.[22] More direct evidence comes from the finding that five of these eight patients who also received an amobarbital injection into the right carotid artery presented with no impairment of semantic comprehension. Additionally, seven of eight patients had other language functions still strongly lateralized to the left hemisphere. This was shown by intracarotid amobarbital testing in all patients and by the impairment of both speech comprehension and production in response to direct cortical electrical stimulation in three of eight patients who also underwent such mapping.[23] In general, the right hemisphere does not appear to normally possess the ability to independently make judgments of semantic relatedness. Evidence for this finding comes from (1) patients who underwent a left hemispherectomy,[24] and (2) lateralized right hemisphere testing of patients who underwent a commissurotomy.[25,26] Therefore, the possibility that the right hemisphere could be performing this function in our subjects seems remote.

Therefore, the significance of these data is the following: the intracarotid amobarbital test can be used reliably only for determining lateralization of speech-production ability and other functions subserved by the anterior circulation. The intracarotid amobarbital test does not reliably assess all of the speech-comprehension functions subserved by the posterior circulation.

More generally, the intracarotid amobarbital test cannot be expected to reliably affect the functions of the posterior territory of the middle cerebral artery. Therefore, conclusions drawn from the intracarotid amobarbital test about the laterality (or lack thereof) of functions thought to be associated with these regions, such as attentional mechanisms,[27] may have to be interpreted with caution.

The practical significance of our data is that the intracarotid amobarbital test cannot be completely relied on to determine the laterality of all language functions, because of the variable perfusion to some regions the dominant hemisphere subservin language and the occurrence of ind viduals in whom speech comprehe sion is not subserved by the sam hemisphere as speech production. This may be important when the po sibility of surgical encroachment o these regions is present, which is no a more frequent possibility in foc cortical resections for epilepsy o tumor.[29] It may necessitate the nee for other diagnostic studies, such a intraoperative and extraoperative direct cortical electrical stimulation fo language localization[30,23] or selectiv amobarbital injection into the posterior cerebral artery.[31]

This investigation has been supported, in par by Teacher-Investigator Award No. 1 K0 NS00721 and grant No. 1 R01 NS26553 from th National Institute of Neurological Disorders an Stroke, Bethesda, Md.

The authors do not have any commercial o proprietary interest in amobarbital or the angiography or electroencephalography equipmen described in this article.

We thank A. Krumholz, MD, S. Uematsu, MD E. Niedermeyer, MD, and B. Carson, MD, Baltimore, Md, for referring their patients, the neuroradiology division for performing the arteriograms and the intracarotid amobarbital injections, Barbara Cysyk and Pamela Sanders fo their assistance in scheduling and patient education, and two anonymous reviewers for their suggestions.

When the world turns upside down...

Transderm Scōp is the better choice for motion sickness prevention

- more effective than 25 mg meclizine and Dramamine®[1,2]
- better compliance because transdermal delivery is more convenient

Transderm Scōp®
scopolamine
programmed delivery
0.5 mg over 72 hrs

Transderm Scōp should not be used in children. Use with special care in the elderly and in patients taking drugs (including alcohol) capable of causing CNS effects. Dryness of the mouth occurs in about two thirds of people. Please see Prescribing Information on next page before prescribing.

CIBA

Transderm Scōp®

scopolamine
(formerly Transderm-V)

Transdermal Therapeutic System

Programmed delivery *in vivo* of 0.5 mg of scopolamine over 3 days

BRIEF SUMMARY (FOR FULL PRESCRIBING INFORMATION, SEE PACKAGE INSERT)

INDICATIONS AND USAGE

Transderm Scōp is indicated for prevention of nausea and vomiting associated with motion sickness in adults. The disc should be applied only to skin in the postauricular area.

Clinical Results: Transderm Scōp provides antiemetic protection within several hours following application of the disc behind the ear. In 195 adult subjects of different racial origins who participated in clinical efficacy studies at sea or in a controlled motion environment, there was a 75% reduction in the incidence of motion-induced nausea and vomiting. Transderm Scōp provided significantly greater protection than that obtained with oral dimenhydrinate.

CONTRAINDICATIONS

Transderm Scōp should not be used in patients with known hypersensitivity to scopolamine or any of the components of the adhesive matrix making up the therapeutic system, or in patients with glaucoma.

WARNINGS

Transderm Scōp should not be used in children and should be used with special caution in the elderly. See **PRECAUTIONS.**

Since drowsiness, disorientation, and confusion may occur with the use of scopolamine, patients should be warned of the possibility and cautioned against engaging in activities that require mental alertness, such as driving a motor vehicle or operating dangerous machinery.

Potentially alarming idiosyncratic reactions may occur with ordinary therapeutic doses of scopolamine.

PRECAUTIONS

General

Scopolamine should be used with caution in patients with pyloric obstruction, or urinary bladder neck obstruction. Caution should be exercised when administering an antiemetic or antimuscarinic drug to patients suspected of having intestinal obstruction.

Transderm Scōp should be used with special caution in the elderly or in individuals with impaired metabolic, liver, or kidney functions, because of the increased likelihood of CNS effects.

Information for Patients

Since scopolamine can cause temporary dilation of the pupils and blurred vision if it comes in contact with the eyes, patients should be strongly advised to wash their hands thoroughly with soap and water immediately after handling the disc.

Patients should be advised to remove the disc immediately and contact a physician in the unlikely event that they experience symptoms of acute narrow-angle glaucoma (pain in and reddening of the eyes accompanied by dilated pupils).

Patients should be warned against driving a motor vehicle or operating dangerous machinery. A patient brochure is available.

Drug Interactions

Scopolamine should be used with care in patients taking drugs, including alcohol, capable of causing CNS effects. Special attention should be given to drugs having anticholinergic properties, e.g., belladonna alkaloids, antihistamines (including meclizine), and antidepressants.

Carcinogenesis, Mutagenesis, Impairment of Fertility

No long-term studies in animals have been performed to evaluate carcinogenic potential. Fertility studies were performed in female rats and revealed no evidence of impaired fertility or harm to the fetus due to scopolamine hydrobromide administered by daily subcutaneous injection. In the highest-dose group (plasma level approximately 500 times the level achieved in humans using a transdermal system), reduced maternal body weights were observed.

Pregnancy Category C

Teratogenic studies were performed in pregnant rats and rabbits with scopolamine hydrobromide administered by daily intravenous injection. No adverse effects were recorded in the rats. In the rabbits, the highest dose (plasma level approximately 100 times the level achieved in humans using a transdermal system) of drug administered had a marginal embryotoxic effect. Transderm Scōp should be used during pregnancy only if the anticipated benefit justifies the potential risk to the fetus.

Nursing Mothers

It is not known whether scopolamine is excreted in human milk. Because many drugs are excreted in human milk, caution should be exercised when Transderm Scōp is administered to a nursing woman.

Pediatric Use

Children are particularly susceptible to the side effects of belladonna alkaloids. Transderm Scōp should not be used in children because it is not known whether this system will release an amount of scopolamine that could produce serious adverse effects in children.

ADVERSE REACTIONS

The most frequent adverse reaction to Transderm Scōp is dryness of the mouth. This occurs in about two thirds of the people. A less frequent adverse reaction is drowsiness, which occurs in less than one sixth of the people. Transient impairment of eye accommodation, including blurred vision and dilation of the pupils, is also observed.

The following adverse reactions have also been reported on infrequent occasions during the use of Transderm Scōp: disorientation; memory disturbances; dizziness; restlessness; hallucinations; confusion; difficulty urinating; rashes and erythema; acute narrow-angle glaucoma; and dry, itchy, or red eyes.

Drug Withdrawal: Symptoms including dizziness, nausea, vomiting, headache and disturbances of equilibrium have been reported in a few patients following discontinuation of the use of the Transderm Scōp system. These symptoms have occurred most often in patients who have used the systems for more than three days.

OVERDOSAGE

Overdosage with scopolamine may cause disorientation, memory disturbances, dizziness, restlessness, hallucinations, or confusion. Should these symptoms occur, the Transderm Scōp disc should be immediately removed. Appropriate parasympathomimetic therapy should be initiated if these symptoms are severe.

DOSAGE AND ADMINISTRATION

Initiation of Therapy: One Transderm Scōp disc (programmed to deliver 0.5 mg of scopolamine over 3 days) should be applied to the hairless area behind one ear at least 4 hours before the antiemetic effect is required. Only one disc should be worn at any time.

Handling: *After the disc is applied on dry skin behind the ear, the hands should be washed thoroughly with soap and water and dried. Upon removal of the disc, it should be discarded, and the hands and application site washed thoroughly with soap and water and dried, to prevent any traces of scopolamine from coming into direct contact with the eyes. (A patient brochure is available.)*

Continuation of Therapy: Should the disc become displaced, it should be discarded, and a fresh one placed on the hairless area behind the other ear. If therapy is required for longer than 3 days, the first disc should be discarded, and a fresh one placed on the hairless area behind the other ear.

The system should be stored between 59°-86°F (15°-30°C).

CAUTION

Federal law prohibits dispensing without prescription.

THIS IS WHAT DUCHENNE MUSCULAR DYSTROPHY GRADUALLY DOES TO A CHILD'S MUSCLES.

It wastes them away.

Duchenne is a "progressive" disease, so the child grows weaker over time. The muscle loss can't be stopped. And it can't be reversed.

The Muscular Dystrophy Association is striving to cure Duchenne. And on Christmas Eve of 1987, in what MDA Chairman Jerry Lewis called "a holiday gift of hope," MDA researchers announced a landmark advance: discovery of the cause of this dread disease.

Now we're directly on the path to a cure for Duchenne. And MDA researchers are racing against time to save the children stricken today.

You can help save these children — and youngsters and adults with other muscle diseases — by making a tax-deductible contribution to MDA. The Association receives no government grants or patient fees for services, so its work is funded entirely by private donations.

Please send your support to MDA today. And maybe soon we'll see Duchenne, not muscles, disappear.

Memory Complaints in Older Adults

Fact or Fiction?

Karen I. Bolla, PhD; Karen N. Lindgren; Cathy Bonaccorsy; Margit L. Bleecker, MD, PhD

• Complaints of poor memory by patients may be an early symptom of a pathologic process like Alzheimer's disease. It is therefore important to determine if patients' complaints of memory impairments are an accurate reflection of real memory disturbance. The relationship between memory complaints (metamemory) and objective memory performance, mood, age, verbal intelligence, and sex was examined in a group of 199 healthy, community dwelling adults (39 to 89 years old). Memory complaints demonstrated a stronger association with depressed mood than with performance on memory tests. Increasing reports of depressive symptoms were associated with more overall memory complaints. Verbal intelligence, age, and sex also contributed to memory complaints. Patients with higher verbal intelligence reported fewer complaints and placed less emphasis on forgetting. Older individuals reported greater frequency of forgetting and greater frequency of using memory techniques. Specific types of memory complaints, seriousness of forgetting, and types of memory aids employed are also described. These results showed that self-rating of memory disturbance by older adults may be related more to depressed mood than to poor performance on memory tests.

(*Arch Neurol.* 1991;48:61-64)

Increasing attention has been focused on Alzheimer's disease both by the scientific community and the media. As a result, health care providers have become more aware and concerned when their patients complain of memory difficulties. Memory disturbance has been associated not only with disease processes such as Alzheimer's disease and cerebrovascular disease but also with metabolic disturbances, toxic effects of medications, and disturbances of mood (ie, depression).[1] Information relating the accuracy of these complaints to actual memory problems could aid the physician in formulating a more accurate diagnosis for their patients who complain of memory difficulties.

The relationship between metamemory (knowledge of one's own memory abilities), age, objective memory performance, and mood states is unclear. Several studies have found older individuals more accurately evaluated their memory performance than younger individuals,[2-4] while others have found exactly the opposite.[5] There is also evidence for no relationship between age and metamemory abilities.[6-8] These inconsistencies appear to be related to the type of memory task employed as well as the wording of questionnaire items.[8-10]

Do patients' memory complaints predict real memory disturbance as measured on objective memory tests? While Riege[4] found individuals with memory complaints were more likely to score low on memory tests, other authors[7,11] have not found a relationship between memory complaints and impaired memory performance. It may be that older individuals experience the same commonplace incidents of forgetfulness as younger individuals, but interpret these incidents as indications of much more serious problems.[7,11] This tendency has been found to be particularly pronounced in depressed individuals.[3,7] Fifty-one percent of patients referred for formal memory testing because of memory complaints were found to have no objective evidence of memory difficulties, but they were found to have significantly depressed mood.[12] In the healthy elderly, Larrabee and Levin[13] found that ratings of decline in memory function were related to affective states rather than to poor performance on a test of everyday memory. In depressed individuals, changes in level of depression, rather than memory skills training, resulted in more positive self-evaluations of memory.[11,14]

The primary aim of this study was to examine the association between memory complaints and performance on standardized neuropsychologic memory tests, mood, sex, native intelligence, and age in a healthy adult community-dwelling population. The prevalence of specific types of memory complaints, ratings of the seriousness of forgetting in specific situations, and the frequency of techniques used to remember things were also examined.

SUBJECTS AND METHODS

Subjects

The subjects were 199 white volunteers (79 men and 120 women), with age ranging from 39 to 89 years (mean, 62 ± 13 years) and education ranging from 7 to 21 years (mean, 15 ± 3 years). The number of sub-

†When you actually forget in these situations, how serious of a problem do you consider memory failure to be?

‡Percent represents only those responding 1, 2, and 3 on the five-point scale (ie, for complaint: 1, always; 3, sometimes; seriousness: 1, very serious; 3, somewhat serious).

jects in each age decade is presented in Table 1. Subjects were included in the study if they never had had head trauma, stroke, seizure, uncontrolled hypertension, pulmonary edema, liver failure, congestive heart failure, uncontrolled thyroid dysfunction, electroconvulsive therapy, sleep disorders, coma, psychiatric disorders, or alcohol/drug abuse. Participants were recruited through newspaper advertisements. This project was approved by the institutional review board and informed consent was obtained following a full explanation of the procedures used in the protocol.

Procedure

A packet of questionnaires was sent to each subject prior to the participant's appointment for a comprehensive neuropsychologic evaluation. Included in the packet were the Geriatric Depression Scale (GDS)[15] and the Metamemory Questionnaire (MMQ).[2] The GDS assesses almost exclusively the psychologic components of depression without somatic complaints. The MMQ[2] is composed of groups of questions related to specific memory categories. The original MMQ was written in a seven-point Likert scale format, but for our purposes, this format was shortened to five points (1, serious problems; 5, no problem). The nine scales measured by the MMQ include: general rating of memory, retrospective evaluation of memory, frequency of forgetting in various situations, ability to remember occurrences recent or remote in time, importance placed on forgetting in various situations, frequency of using various mnemonics, ability to recall what is read in a novel, newspaper, or magazine article, and effort expended to avoid forgetting. Neuropsychologic measures included the Wechsler Adult Intelligence Scale-Revised vocabulary subtest that provides a measure of verbal intelligence[16]; Immediate and Delayed Logical Memory (memory for a short story) and visual reproduction (memory for geometric designs) from the Wechsler Memory Scale[17]; Verbal-Verbal Paired Associates Learning Test (hard associates)[18]; and the Rey Auditory Verbal Learning Test[19] (memory for a 15-item word list presented over five trials).

RESULTS

The average scores on the GDS, MMQ, and memory tests are presented in Table 2. The relationship between metamemory and depression, age, sex, education, verbal intelligence, and memory test performance was evaluated using a stepwise multiple regression. Regressions were performed on the total metamemory scale score as well as the nine individual MMQ scales. A forward stepping entry procedure was used and an F of 4.00 was required for factor entry. The results are given in Table 3. Higher scores on the GDS (greater depression) were as-

Table 5.—Frequency of Techniques Used to Remember Things

	%
Keep an appointment book	69
Make a grocery list	63
Keep things to do in a prominent place where you will notice them	62
Write reminder notes	59
Make lists	59
Keep objects in an identical place so you always know where to find them	58
Plan daily schedule in advance	43

Have others remind you	20

sociated with greater complaints on eight of the nine individual MMQ scales and greater memory complaints overall. Verbal intelligence was related to the total score, the reported frequency of forgetting, and the importance placed on forgetting. Those at higher vocabulary levels reported fewer complaints and placed less importance on forgetting. Age was related to the frequency of forgetting and the frequency of using mnemonic devices. Older subjects reported a higher frequency of forgetting and reported using more mnemonic devices than younger subjects. More women than men reported using memory techniques.

The performance on the logical memory test (paragraph recall) and delayed logical memory test was related to the ease of remembering written material (a novel or a newspaper). When the prevalence of memory complaints was examined, only 19% of the 199 subjects reported no memory complaints. While no age trend was found for the frequency of *total* memory complaints, an aging trend was found for General Rating of Memory (M1). Memory difficulty was reported by 73% of the 40-year-old subjects, 80% of the 50-year-old subjects, 84% of the 60-year-old subjects, 91% of the 70-year-old subjects, and 79% of the 80-year-old subjects.

The specific situations in which memory problems were reported to occur and the rating of their seriousness is given in Table 4. Although forgetting names and forgetting where objects have been placed were reported most frequently, these were not considered serious problems. Instead, losing the thread of thought in conversation and forgetting appointments occurred less often but were believed to be more serious when the situation occurred. There was no change in the frequency of forgetting or concern in specific situations as a function of age. Table 5 lists the frequency in which specific techniques are used to remember things. Written documentation (ie, appointment books, notes, lists) is used most frequently, while relying on others for reminders is the least used memory aid.

COMMENT

Memory complaints in healthy community-dwelling older adults were related more to depressed mood than to performance on objective memory tests. Verbal intelligence, age, and sex were associated with the reporting of memory disturbance. These results agree with those found by other investigators.[3,12,13,20]

Depressed mood is generally associated with diminished ability to think or to concentrate.[21] These attention and concentration difficulties are often misinterpreted as memory disturbance by the patient. Once the distinction between disturbances in concentration vs memory disturbance is discussed with the patient, their fear of having a disease like Alzheimer's is quickly alleviated. It should be kept in mind that none of our subjects would be considered clinically depressed, and therefore these results indicate that even mild complaints of depressed mood appear to influence perceptions of memory.

Questions on the MMQ relating to frequency of forgetting while reading a novel, newspaper, or magazine were positively correlated with performance on the logical memory test (immediate and delayed recall). This relationship could be related to the fact that text recall after only one presentation of the material is more susceptible to disturbances in attention/concentration, a concomitant of depressed mood, than the other memory tasks where the material was given to the participant more than once. A similar interpretation was offered by Larrabee and Levin[22] in their investigation of the association of memory report and performance. A relationship between subjective memory reports and performance on memory tests has previously been found for text or story recall, a common everyday activity.[4,23] Additionally, if material cannot be remembered immediately after it is presented, then poor retention (delayed recall) would also be expected.

The participants with higher verbal intelligence reported fewer total complaints, less forgetting, and placed less emphasis on forgetting. One hypothesis may be that those who have read more are better informed about the aging process as well as diseases such as Alzheimer's and may recognize everyday memory problems as nonserious rather than as a sign of dementia. Education level did not enter any of the regression equations. Bolla-Wilson and Bleecker[24] have suggested that vocabulary level is more appropriate than education level when studying older adults. Older individuals may not have had many formal years of education but may have spent many years self-educating.

Although some researchers have suggested that the elderly have difficulty forming effective strategies to help them recall, others have found that "coaching" the elderly in useful strategies improved memory performance.[8] In our sample, the older adults tended to use more mnemonic strategies to help in their recall. The most frequently used techniques included writing notes, making lists, and keeping objects and things in specific places so they could be easily found. Since the majority of our subjects tended to be well educated with average and above average levels of verbal intelligence, this could account for their tendency to formulate their own memory techniques for more effective recall.

Whereas age was not associated with the total number of complaints on the MMQ, age was associated with a greater frequency of forgetting in various situations. While the most common complaints were in the ability to remember names, where objects were placed, and telephone numbers, these were not considered to be the most serious situations. The most serious situations were reported to be losing the thread of thought in conversation and forgetting appointments (although these occurred less frequently). Since reports of forgetting were not related to actual memory ability, it appears that older adults may be more "fine tuned" to situations in which they forget, whereas younger individuals pay less attention to common memory problems.[7]

The ability to remember occurrences, both recent and remote in time, was correlated with the GDS. Older individuals may compare present memory ability with their own past ability, rather than comparing memory ability with individuals their own age. Retrospective comparison produces feelings of inadequacy: normal changes in memory ability are ignored as well as the fact that when younger, one practices memory skills when in school or on a job. Additionally, only a small percent (19%) of our population

failed to report memory complaints. In summary, these results suggest that self-reported memory complaints in healthy older adults appear to be more closely associated with depressed mood than with actual memory performance on standard clinical memory tests.

ANTICONVULSANT BULLETIN

New evidence: No difference between the cognitive effects of phenytoin and carbamazepine

Turn page for the results of an important new study.

ANTICONVULSANT BULLETIN

Results from:
Comparative cognitive effects of anticonvulsants

K.J. Meador, D.W. Loring, K. Huh, B.B. Gallagher, D.W. King
Neurology. 1990;40:391-394.

Patients receiving phenytoin and carbamazepine had virtually identical cognitive performances[1]

- Fifteen seizure patients treated with phenytoin, carbamazepine, and phenobarbital for 3 months each were given a cognitive evaluation at the end of each treatment period[1]
- Cognitive tests were designed to assess deficits associated with anticonvulsants—impairments in memory, information processing, attention/concentration, and motor speed[1]
- Mean cognitive scores and individual responses failed to suggest a trend toward differential effects[1]

Mean scores* for cognitive measures

Cognitive Measures	Carbamazepine	Phenytoin	Phenobarbital
Grapho-Motor Coding	48	48	43
Simple Attention†	5.5	5.5	5.7
Simple Attention‡	4.0	4.5	4.5
Selective Reminding Test	53	59	49
Repetitive Motor Speed	46	45	44
Coordination/Motor Speed	72	73	74
Decisional/Motor Speed	698	705	737

—adapted from Meador et al, p 392[1]

*On Decisional/Motor Speed, it was desirable to achieve as *low* a score as possible. On all other tests, it was desirable to achieve as *high* a score as possible. However, there was no significant difference between scores of the three anticonvulsants on any test with the exception of Grapho-Motor Coding—the score for phenobarbital was significantly worse than for the other two anticonvulsants

†Digit Span Forward. ‡Digit Span Backward

Rigorous study design helped prevent patient selection bias—a flaw of most earlier studies

- Randomized, double-blind, triple-crossover study design helped prevent patient selection bias[1]
- Dosages were adjusted to be within the standard therapeutic range (phenytoin, 10 to 20 μg/mL; carbamazepine, 6 to 12 μg/mL; phenobarbital, 15 to 40 μg/mL)[1]

This information is brought to you by Parke-Davis, maker of

Dilantin® Kapseals®

(extended phenytoin sodium capsules, USP) 100 mg

Dilantin® KAPSEALS® (Extended Phenytoin Sodium Capsules, USP)

Before prescribing, please see full prescribing information. A Brief Summary follows.

INDICATIONS AND USAGE: Dilantin is indicated for the control of generalized tonic-clonic (grand mal) and complex partial (psychomotor, temporal lobe) seizures and prevention and treatment of seizures occurring during or following neurosurgery.

Phenytoin serum level determinations may be necessary for optimal dosage adjustments (see Dosage and Administration and Clinical Pharmacology in the full prescribing information).

CONTRAINDICATIONS: Phenytoin is contraindicated in those patients who are hypersensitive to phenytoin or other hydantoins.

WARNINGS: Abrupt withdrawal of phenytoin in epileptic patients may precipitate status epilepticus. When, in the judgment of the clinician, the need for dosage reduction, discontinuation, or substitution of alternative antiepileptic medication arises, this should be done gradually. However, in the event of an allergic or hypersensitivity reaction, rapid substitution of alternative therapy may be necessary. In this case, alternative therapy should be an antiepileptic drug not belonging to the hydantoin chemical class.

There have been a number of reports suggesting a relationship between phenytoin and the development of lymphadenopathy (local or generalized) including benign lymph node hyperplasia, pseudolymphoma, lymphoma, and Hodgkin's Disease. Although a cause and effect relationship has not been established, the occurrence of lymphadenopathy indicates the need to differentiate such a condition from other types of lymph node pathology. Lymph node involvement may occur with or without symptoms and signs resembling serum sickness, eg, fever, rash and liver involvement.

In all cases of lymphadenopathy, follow-up observation for an extended period is indicated and every effort should be made to achieve seizure control using alternative antiepileptic drugs.

Acute alcoholic intake may increase phenytoin serum levels while chronic alcoholic use may decrease serum levels.

In view of isolated reports associating phenytoin with exacerbation of porphyria, caution should be exercised in using this medication in patients suffering from this disease.

Usage in Pregnancy: A number of reports suggests an association between the use of antiepileptic drugs by women with epilepsy and a higher incidence of birth defects in children born to these women. Data are more extensive with respect to phenytoin and phenobarbital, but these are also the most commonly prescribed antiepileptic drugs; less systematic or anecdotal reports suggest a possible similar association with the use of all known antiepileptic drugs.

The reports suggesting a higher incidence of birth defects in children of drug-treated epileptic women cannot be regarded as adequate to prove a definite cause and effect relationship. There are intrinsic methodological problems in obtaining adequate data on drug teratogenicity in humans; genetic factors or the epileptic condition itself may be more important than drug therapy in leading to birth defects. The great majority of mothers on antiepileptic medication deliver normal infants. It is important to note that antiepileptic drugs should not be discontinued in patients in whom the drug is administered to prevent major seizures, because of the strong possibility of precipitating status epilepticus with attendant hypoxia and threat to life. In individual cases where the severity and frequency of the seizure disorder are such that the removal of medication does not pose a serious threat to the patient, discontinuation of the drug may be considered prior to and during pregnancy, although it cannot be said with any confidence that even minor seizures do not pose some hazard to the developing embryo or fetus. The prescribing physician will wish to weigh these considerations in treating or counseling epileptic women of childbearing potential.

Dilantin® Kapseals®
(extended phenytoin sodium capsules, USP)

In addition to the reports of increased incidence of congenital malformation, such as cleft lip/palate and heart malformations, in children of women receiving phenytoin and other antiepileptic drugs, there have more recently been reports of a fetal hydantoin syndrome. This consists of prenatal growth deficiency, microcephaly and mental deficiency in children born to mothers who have received phenytoin, barbiturates, alcohol, or trimethadione. However, these features are all interrelated and are frequently associated with intrauterine growth retardation from other causes.

There have been isolated reports of malignancies, including neuroblastoma, in children whose mothers received phenytoin during pregnancy.

An increase in seizure frequency during pregnancy occurs in a high proportion of patients, because of altered phenytoin absorption or metabolism. Periodic measurement of serum phenytoin levels is particularly valuable in the management of a pregnant epileptic patient as a guide to an appropriate adjustment of dosage. However, postpartum restoration of the original dosage will probably be indicated.

Neonatal coagulation defects have been reported within the first 24 hours in babies born to epileptic mothers receiving phenobarbital and/or phenytoin. Vitamin K has been shown to prevent or correct this defect and has been recommended to be given to the mother before delivery and to the neonate after birth.

PRECAUTIONS: General: The liver is the chief site of biotransformation of phenytoin; patients with impaired liver function, elderly patients, or those who are gravely ill may show early signs of toxicity.

A small percentage of individuals who have been treated with phenytoin has been shown to metabolize the drug slowly. Slow metabolism may be due to limited enzyme availability and lack of induction; it appears to be genetically determined.

Phenytoin should be discontinued if a skin rash appears (see "Warnings" section regarding drug discontinuation). If the rash is exfoliative, purpuric, or bullous or if lupus erythematosus, Stevens-Johnson syndrome, or toxic epidermal necrolysis is suspected, use of this drug should not be resumed and alternative therapy should be considered. (See Adverse Reactions.) If the rash is of a milder type (measles-like or scarlatiniform), therapy may be resumed after the rash has completely disappeared. If the rash recurs upon reinstitution of therapy, further phenytoin medication is contraindicated.

Phenytoin and other hydantoins are contraindicated in patients who have experienced phenytoin hypersensitivity. Additionally, caution should be exercised if using structurally similar (eg, barbiturates, succinimides, oxazolidinediones and other related compounds) in these same patients.

Hyperglycemia, resulting from the drug's inhibitory effects on insulin release, has been reported. Phenytoin may also raise the serum glucose level in diabetic patients.

Osteomalacia has been associated with phenytoin therapy and is considered to be due to phenytoin's interference with Vitamin D metabolism.

Phenytoin is not indicated for seizures due to hypoglycemic or other metabolic causes. Appropriate diagnostic procedures should be performed as indicated.

Phenytoin is not effective for absence (petit mal) seizures. If tonic-clonic (grand mal) and absence (petit mal) seizures are present, combined drug therapy is needed.

Serum levels of phenytoin sustained above the optimal range may produce confusional states referred to as "delirium," "psychosis," or "encephalopathy," or rarely irreversible cerebellar dysfunction. Accordingly, at the first sign of acute toxicity, plasma levels are recommended. Dose reduction of phenytoin therapy is indicated if plasma levels are excessive; if symptoms persist, termination is recommended. (See Warnings.)

Information for Patients: Patients taking phenytoin should be advised of the importance of adhering strictly to the prescribed dosage regimen, and of informing the physician of any clinical condition in which it is not possible to take the drug orally as prescribed, eg, surgery, etc.

Patients should also be cautioned on the use of other drugs or alcoholic beverages without first seeking the physician's advice.

Patients should be instructed to call their physician if skin rash develops.

The importance of good dental hygiene should be stressed in order to minimize the development of gingival hyperplasia and its complications.

Do not use capsules which are discolored.

Laboratory Tests: Phenytoin serum level determinations may be necessary to achieve optimal dosage adjustments.

Drug Interactions: There are many drugs which may increase or decrease phenytoin levels or which phenytoin may affect. Serum level determinations for phenytoin are especially helpful when possible drug interactions are suspected. The most commonly occurring drug interactions are listed below: 1. Drugs which may increase phenytoin serum levels include: acute alcohol intake, amiodarone, chloramphenicol, chlordiazepoxide, diazepam, dicumarol, disulfiram, estrogens, H_2-antagonists, halothane, isoniazid, methylphenidate, phenothiazines, phenylbutazone, salicylates, succinimides, sulfonamides, tolbutamide, trazodone.

2. Drugs which may decrease phenytoin levels include: carbamazepine, chronic alcohol abuse, reserpine, and sucralfate. Moban® brand of molindone hydrochloride contains calcium ions which interfere with the absorption of phenytoin. Ingestion times of phenytoin and antacid preparations containing calcium should be staggered in patients with low serum phenytoin levels to prevent absorption problems.

3. Drugs which may either increase or decrease phenytoin serum levels include: phenobarbital, sodium valproate, and valproic acid. Similarly, the effect of phenytoin on phenobarbital, valproic acid and sodium valproate serum levels is unpredictable.

4. Although not a true drug interaction, tricyclic antidepressants may precipitate seizures in susceptible patients and phenytoin dosage may need to be adjusted.

5. Drugs whose efficacy is impaired by phenytoin include: corticosteroids, coumarin anticoagulants, digitoxin, doxycycline, estrogens, furosemide, oral contraceptives, quinidine, rifampin, theophylline, vitamin D.

Drug/Laboratory Test Interactions: Phenytoin may cause decreased serum levels of protein-bound iodine (PBI). It may also produce lower than normal values for dexamethasone or metyrapone tests. Phenytoin may cause increased serum levels of glucose, alkaline phosphatase, and gamma glutamyl transpeptidase (GGT).

Carcinogenesis: See "Warnings" section for information on carcinogenesis.

Pregnancy: See Warnings.

Nursing Mothers: Infant breast-feeding is not recommended for women taking this drug because phenytoin appears to be secreted in low concentrations in human milk.

ADVERSE REACTIONS: Central Nervous System: The most common manifestations encountered with phenytoin therapy are referable to this system and are usually dose-related. These include nystagmus, ataxia, slurred speech, decreased coordination and mental confusion. Dizziness, insomnia, transient nervousness, motor twitchings, and headaches have also been observed. There have also been rare reports of phenytoin induced dyskinesias, including chorea, dystonia, tremor and asterixis, similar to those induced by phenothiazine and other neuroleptic drugs.

A predominantly sensory peripheral polyneuropathy has been observed in patients receiving long-term phenytoin therapy.

Gastrointestinal System: Nausea, vomiting, constipation, toxic hepatitis and liver damage.

Integumentary System: Dermatological manifestations sometimes accompanied by fever have included scarlatiniform or morbilliform rashes. A morbilliform rash (measles-like) is the most common; other types of dermatitis are seen more rarely. Other more serious forms which may be fatal have included bullous, exfoliative or purpuric dermatitis, lupus erythematosus, Stevens-Johnson syndrome, and toxic epidermal necrolysis (see Precautions).

Hemopoietic System: Hemopoietic complications, some fatal, have occasionally been reported in association with administration of phenytoin. These have included thrombocytopenia, leukopenia, granulocytopenia, agranulocytosis, and pancytopenia with or without bone marrow suppression. While macrocytosis and megaloblastic anemia have occurred, these conditions usually respond to folic acid therapy. Lymphadenopathy including benign lymph node hyperplasia, pseudolymphoma, lymphoma, and Hodgkin's Disease have been reported (see Warnings).

Connective Tissue System: Coarsening of the facial features, enlargement of the lips, gingival hyperplasia, hypertrichosis and Peyronie's Disease.

Cardiovascular: Periarteritis nodosa.

Immunologic: Hypersensitivity syndrome (which may include, but is not limited to, symptoms such as arthralgias, eosinophilia, fever, liver dysfunction, lymphadenopathy or rash), systemic lupus erythematosus, immunoglobulin abnormalities.

OVERDOSAGE: The lethal dose in children is not known. The lethal dose in adults is estimated to be 2 to 5 grams. The initial symptoms are nystagmus, ataxia, and dysarthria. Other signs are tremor, hyperreflexia, lethargy, slurred speech, nausea, vomiting. The patient may become comatose and hypotensive. Death is due to respiratory and circulatory depression.

There are marked variations among individuals with respect to phenytoin plasma levels where toxicity may occur. Nystagmus, on lateral gaze, usually appears at 20 mcg/mL, ataxia at 30 mcg/mL, dysarthria and lethargy appear when the plasma concentration is over 40 mcg/mL, but as high a concentration as 50 mcg/mL has been reported without evidence of toxicity. As much as 25 times the therapeutic dose has been taken to result in a serum concentration over 100 mcg/mL with complete recovery.

Treatment: Treatment is nonspecific since there is no known antidote.

The adequacy of the respiratory and circulatory systems should be carefully observed and appropriate supportive measures employed. Hemodialysis can be considered since phenytoin is not completely bound to plasma proteins. Total exchange transfusion has been used in the treatment of severe intoxication in children.

In acute overdosage the possibility of other CNS depressants, including alcohol, should be borne in mind.

Caution – Federal law prohibits dispensing without prescription. 0362G280

Antibodies to Myelin-Associated Glycoprotein Are Found in Cerebrospinal Fluid in Polyneuropathy Associated With Monoclonal Serum IgM

Mabel Cruz, MD; Yu-Ping Jiang, MD; Jan Ernerudh, MD, PhD; Göran Solders, MD, PhD;
Tomas Olsson, MD, PhD; Per-Olov Osterman, MD, PhD; Hans Link, MD, PhD

• Antibodies to myelin-associated glycoprotein (MAG) have been demonstrated in the serum samples from about half the patients with polyneuropathy associated with serum IgM monoclonal component. We examined cerebrospinal fluid (CSF) and serum samples from 13 patients with this disease by enzyme-linked immunosorbent assay for anti-MAG IgM antibodies. We detected these antibodies in both CSF and serum samples in 10 of the patients; in three of them the antibodies were at higher levels in the CSF. The remaining three patients had anti-MAG IgM antibodies in the CSF only. Intrathecal production of anti-MAG IgM antibodies is thus common in polyneuropathy associated with IgM monoclonal component. In three patients, examined on two occasions from 1 to 7 years, high anti-MAG IgM antibody levels persisted in CSF and serum samples. Among 165 patients with other neurologic diseases, including 60 with multiple sclerosis and 60 control subjects with tension headache, anti-MAG IgM antibodies were detected in the CSF from three patients (two with multiple sclerosis, one with aseptic meningitis), and in the serum sample of one patient with multiple sclerosis. Whether the frequent occurrence of anti-MAG IgM antibodies in CSF and their intrathecal synthesis has pathogenetic relevance for the development of polyneuropathy associated with IgM monoclonal component is unsure.

(*Arch Neurol.* 1991;48:66-70)

Polyneuropathy and monoclonal gammopathy of unknown significance are associated,[1,2] and a causal relationship between serum IgM monoclonal component and polyneuropathy has been suggested.[3-7] In about 50% of patients with IgM monoclonal component in serum, the monoclonal IgM has been shown to bind to myelin structures, mainly myelin-associated glycoprotein (MAG),[5,7-9] glycolipids,[10-12] and a 25- to 30-kd peripheral nerve myelin protein.[13-15] Direct injection of serum samples containing monoclonal component together with complement into nerves of appropriate species induces demyelination,[16,17] while systemic injection has not been shown to produce disease despite long-term observation and treatment.[18] The pathogenetic role of antibodies directed against nervous tissue components is, however, not clear in view of (1) occurrence of such antibodies in normal individuals without disease[15,19]; (2) about 50% of polyneuropathy patients with IgM monoclonal component have no defined antibody activity against myelin components; and (3) the failure of disease induction in systemic passive transfer experiments.[18]

In nerve biopsy specimens[20] and in skin biopsy specimens containing nerve fibers,[21] deposits of IgM have been found. Thus, IgM antibodies of putative pathogenetic importance must in some way have reached the endoneurium in spite of the blood-nerve barrier. One mechanism for this could be by local IgM antibody production. To our knowledge, there are no previous studies on antibodies directed against myelin components in the cerebrospinal fluid (CSF) of patients with polyneuropathy and monoclonal IgM component. We describe that anti-MAG IgM antibodies, when present in serum samples from patients with polyneuropathy, are regularly found in CSF, and may even occur in CSF exclusively.

PATIENTS, MATERIALS, AND METHODS

Patients

Thirteen patients (seven women) had chronic sensory/motor polyneuropathy and IgM monoclonal component in serum samples as defined by agarose electrophoresis and immunofixation. A summary of serum and CSF findings is presented in Table 1. The age of the patients varied between 4 and 83 years (mean, 71 years). Patients and 11 had Waldenström's disease, whereas the others had monoclonal gammopathy of unknown significance. Moderate to severe reduction in nerve conduction velocity was present in all patients except patient 3 in whom neurophysiologic signs of denervation were more prominent.

In addition, 16 patients (five women) with polyneuropathy and serum monoclonal component of IgG isotype in 14 patients and of IgA isotype in two patients were examined. The age of the patients ranged from 41 to 83 years (mean, 70 years).

Control subjects consisted of 165 patients (99 women). Their ages ranged from 20 to 8 years (mean, 67 years). Forty-three of the patients had polyneuropathy without monoclonal component in the serum samples, nine had chronic inflammatory demyelinating polyneuropathy, 14 had acute Guillain-Barré syndrome, 60 had clinically definite multiple sclerosis, 14 had acute aseptic meningitis, 20 had lymphocytic meningoradiculitis (Lyme neuroborreliosis), and five had cerebrovascular disease. The polyneuropathy was due to diabetes in two patients, Refsum's syndrome in one, alcoholism in two, vitamin B_{12} deficiency in two, malignancy in one, sarcoidosis in one, Charcot-Marie-Tooth disease in one, was of unknown cause in thirty-one, and was probably hereditary, but not classified, in two.

Sixty subjects (38 women) who had tension headache and no evidence of organic neurologic diseases constituted our "normal" control subjects. Their ages ranged from 20 to 68 years (mean, 43 years). All 60 subjects had normal findings on routine CSF examinations for cell count, CSF:serum albumin ratio, IgG index, and agarose isoelectric focusing for IgG.

Preparation of MAG

Bovine MAG was prepared by the lithium diiodosalicylatephenol method[22] from brain myelin.[23] One single band migrating at 100 kd appeared after sodium dodecyl sulfate electrophoresis,[24] showing the purity of the preparation.

CSF Studies

The CSF cells were counted by phase contrast microscopy. The IgG and albumin levels were measured by immunoprecipitation nephelometry, and IgA and IgM levels were determined by enzyme-linked immu-

†IgM index equal to (CSF/serum IgM):(CSF/serum albumin).[25]

nosorbent assay (ELISA).[25] The CSF:serum albumin ratio was determined as a variable of the blood-brain barrier state.[26] For documentation of intrathecal immunoglobulin synthesis, CSF IgG index was calculated,[26] as were corresponding IgA and IgM indexes.[25]

ELISA for Detection of Anti-MAG IgM and IgG Antibodies

Ninety-six polystyrene microtiter plates (Dynatech M-129B, Dynatech, Zug, Switzerland) were coated overnight at 4°C with 100-μL aliquots containing 1 μg/mL of purified bovine MAG dissolved in phosphate-buffered saline (PBS), and thereafter washed five times in PBS containing 0.05% Tween 20. Wells were blocked with 200-μL per well of PBS containing 2% bovine serum albumin (Sigma Chemical Co, St Louis, Mo). Samples (100 μL) of serum and CSF adjusted to 1 mg/L of IgM were incubated overnight at 4°C. This IgM concentration yielded optimal discrimination between a positive control serum sample and the negative control consisting of pooled normal serum samples. The CSF samples with IgM concentrations less than 1 mg/L were applied undiluted, except for the addition of 20 μL of PBS per 100 μL of CSF. After washing, alkaline phosphatase-conjugated rabbit anti-human IgM antiserum (μ-chain specific, Dako, Copenhagen, Denmark) diluted 1:2000 was added. After incubation at room temperature for 2 hours, plates were washed and incubated with 100 μL per well of substrate *p*-nitrophenylphosphate (1 mg/mL; Sigma Chemical Co) in 10% diethanolamine and 0.02% magnesium chloride buffer, pH 9.8. Plates were read in an automated ELISA spectrophotometer at 405 nm. The enzyme reaction was allowed to continue until an absorbance value of 1.2 was reached for the positive control. Pooled normal serum samples never gave absorbance values above 0.08. Samples were considered positive when the absorbance value was higher than +3 SD of the mean value obtained from analysis of serum samples and CSF from 60 subjects with tension headache. The range of absorbance values for these serum samples was 0 to 0.10 (mean, 0.023) and the range for corresponding CSF samples was 0 to 0.077 (mean, 0.014), yielding a mean value +3 SD of 0.11 for serum samples and 0.08 for CSF.

For detection of anti-MAG IgG antibodies, 96-well polyvinylchloride microtiter plates (Dynatech) were used; coating concentration of MAG was 3 μg/mL; CSF and serum IgG concentrations were adjusted to 10 μg/mL with PBS containing 1% bovine serum albumin; antiserum consisted of alkaline phosphatase-conjugated rabbit anti-human IgG (γ-chain specific, Dako) diluted 1:1000. Plates were read when an absorbance value of about 0.35 was reached for a "positive" control consisting of a serum sample from a patient with aseptic meningitis. Pooled normal serum samples used as negative controls never gave absorbance values higher than 0.03. Samples were considered positive when the absorbance value was higher than +3 SD of the mean value obtained from analysis of serum samples and CSF from 43 subjects with tension headache. Range of absorbance values for these serum samples was from 0 to 0.051 and for CSF from 0 to 0.058, yielding a mean value +3 SD of 0.06 for serum samples and 0.07 for CSF.

Preliminary studies showed no difference when comparing bovine MAG and human MAG as antigen in ELISA.

Western Blot

To confirm the presence of anti-MAG antibodies, we examined serum samples and CSF specimens by Western blot. The CSF specimens of patients 1b, 4, and 5b (Table 1) were concentrated by air pressure using microcollodion bags (Sartorius, Göttingen, Federal Republic of Germany) to achieve an IgM concentration of 600 to 1000 mg/L. Because of the small volumes available, additional CSF specimens could not be examined. Myelin-associated glycoprotein was subjected to sodium dodecyl sulfate electrophoresis in 12.5% polyacrylamide slab gel,[24] followed by transfer to nitrocellulose membranes (0.45-μm pore size; Schleicher & Schull, Kassel, Federal Republic of Germany).[27] The strips containing MAG were then incubated with a 1:100 diluted patient's serum sample or a 1:5 dilution of the patient's concentrated CSF overnight at room temperature on a shaker platform. After several washes in PBS, strips were incubated with rabbit anti-human IgM (μ-chain specific), rabbit anti-human IgG (γ-chain specific) or rabbit anti-human IgA (α-chain specific) antiserum (Dako) diluted 1:500 in the same buffer, followed by immunoenzyme staining.[28] The same positive and negative controls were used in Western blot as for anti-MAG IgM ELISA.

Demonstration of Anti-MAG IgM Antibodies in Relation to Monoclonal IgM in CSF and Serum by Agarose Isoelectric Focusing and Protein Transfer to Nitrocellulose Membrane

To detect total IgM, serum and CSF samples were analyzed after mild reduction with β-mercaptoethanol. Briefly, 5 μg of IgM were mixed with 10 μL of 0.8 mol/L of β-mercaptoethanol (Sigma) and 80 μL of PBS. This mixture was incubated for 13 to 15 minutes. Fifteen microliters of this preparation were subjected to agarose isoelectric focusing.[28] Separation of proteins was performed for 70 minutes at 15 W. Voltage was increased every 20 minutes

Table 2.—Number of Patients Positive vs Examined for Anti-MAG IgM and IgG Antibodies in Cerebrospinal Fluid (CSF) and Serum Samples as Determined by ELISA, and in Serum Samples Only Evaluated by Western Blot*

	ELISA				Western Blot	
	IgM		IgG		Serum Samples

*MAG indicates myelin-associated glycoprotein; ELISA, enzyme-linked immunosorbent assay; M, monoclonal; ND, not done; and CIDP, chronic inflammatory demyelinating polyneuropathy.

starting from 200 V (50 mA) and finishing at 800 V (18 mA). Separated proteins were transferred to nitrocellulose membrane, followed by incubation in PBS containing 1:500 diluted peroxidase-conjugated $(Fab')_2$ fragment of goat anti-human IgM (μ-chain specific, Sigma), and then stained.[28]

To detect anti-MAG IgM antibodies, nitrocellulose membranes were coated overnight at room temperature in 10 μg/mL of MAG in PBS, followed by blocking with 3% bovine serum albumin in PBS for 1 hour. After agarose isoelectric focusing, separated proteins were transferred to MAG-coated nitrocellulose membrane[29] and antibodies bound were detected by immunoenzyme labeling as for total IgM.

Patterns of anti-MAG IgM antibody were compared with those of total IgM obtained in parallel on the same specimens.

RESULTS

A survey of CSF and serum findings for the 13 patients with polyneuropathy and serum IgM monoclonal component is presented in Table 1. All 13 patients had normal CSF cell counts that varied between 1 and 2×10^6/L. Nine patients had elevated CSF:serum albumin ratio as a sign of damage to blood-brain barrier or blood-nerve barrier in the area of nerve roots. Seven patients had increased IgM index, reflecting intrathecal production of IgM. The IgG index was normal in all patients, while the elevated IgA index was registered in five.

Anti-MAG Antibodies Detected by ELISA

Three of the 13 patients with polyneuropathy and IgM monoclonal component had anti-MAG IgM antibodies in CSF only (patients 3, 11, and 13, Table 1). In the remaining 10 patients, anti-MAG IgM antibodies were present in CSF and serum samples, but three of them (patients 1a, 5b, and 12) had higher absorbance values in CSF than in the serum samples. Evidence was thus obtained for intrathecal production of anti-MAG IgM antibodies in six of the 13 patients with polyneuropathy and IgM monoclonal component.

In patients 1, 5, and 8, two consecutive CSF and serum samples covering 1 to 7 years were examined. Anti-MAG IgM antibodies were detected in all consecutive specimens in both compartments.

One of the 14 patients with polyneuropathy and IgG monoclonal component and one of the two patients with polyneuropathy and IgA monoclonal component also had anti-MAG antibodies of IgM isotype (Table 2, Fig 1). These antibodies were present in CSF only, reflecting intrathecal synthesis.

Among the patients of the different control groups, anti-MAG IgM antibodies were found in CSF from two (3%) of the 60 patients with multiple sclerosis and from one (7%) of the 14 patients with aseptic meningitis, and in the serum sample from one patient (2%) with multiple sclerosis (Table 2, Fig 1).

Slightly elevated absorbance values for anti-MAG antibodies of the IgG isotype were observed in the serum sample from one patient with polyneuropathy and IgG monoclonal component, five patients with polyneuropathy without serum monoclonal component, two with chronic inflammatory demyelinating polyneuropathy, and three with multiple sclerosis (Table 2). In CSF, only one patient with multiple sclerosis had anti-MAG IgG antibodies.

The two patients with polyneuropathy and IgA monoclonal component were examined for anti-MAG antibodies of the IgA isotype in CSF and serum samples, with negative results.

Anti-MAG Antibody Reactivity Detected by Western Blot

Western blot confirmed the presence of anti-MAG IgM antibodies in serum samples from eight of 10 patients with polyneuropathy and IgM monoclonal component who were positive by ELISA (Table 1). The remaining three patients were negative by ELISA and also when examined by Western blot. No anti-MAG reactivity was found by Western blot in nine additional serum samples from two of the control groups (Table 2).

Due to the low IgM levels in CSF compared with serum samples, it was not possible to study CSF specimens by Western blot, except in three patients with polyneuropathy and serum IgM monoclonal component (patients 1b, 4, and 5b). Anti-MAG IgM antibody reactivity was detected in two of these three CSF specimens as exemplified for patient 4 in Fig 2. Anti-MAG antibody reactivity appeared as a faint band on the blots incubated with CSF samples when compared with the strong band seen on the blots of serum samples from the same patient, probably due to differences in the IgM concentration between serum and CSF samples.

Relationship Between IgM Monoclonal Components and Anti-MAG IgM Antibody Activity

Serum and concentrated CSF specimens from patients 1b, 4, and 5b (Table 1) and serum specimens from patients 7 and 8b (Table 1) were analyzed for anti-MAG antibody reactivity after separation by agarose isoelectric focusing. Such antibody reactivity was detected in all specimens examined and localized to the IgM monoclonal components as visualized in Fig 2 for CSF and serum samples from patient 4.

COMMENT

In samples from 29 patients with polyneuropathy and serum monoclonal component, anti-MAG IgM antibodies were detected by ELISA in all 13 patients who had monoclonal component of IgM isotype. In three of these patients, anti-MAG IgM antibodies were present in CSF only, while the remaining 10 patients had antibodies in CSF and serum samples (Table 1). Among the 16 patients with polyneuropathy and monoclonal component of IgG or IgA isotype, anti-MAG IgM antibodies were present only in two patients and in CSF exclusively (Table 2). None of our control subjects with polyneuropathy without serum monoclonal component had anti-MAG IgM antibodies detected by ELISA.

We used a standardized IgM concentration in the ELISA for anti-MAG and may therefore anticipate intrathecal anti-MAG IgM antibody synthesis in patients where CSF absorbance values exceed serum values (Table 1). This was the case in six of the 13 patients with IgM monoclonal component. We therefore propose that patients with polyneuropathy and IgM monoclonal component also be examined for anti-MAG IgM antibodies in CSF. Further studies on larger patient groups are, however, warranted to evaluate the diagnostic and therapeutic implications of such examinations.

When injected directly into peripheral nerves of suitable species, anti-MAG antibodies of the IgM isotype produced demyelination.[16,17] These observations reinforce the possibility that intrathecal production of these antibodies, as we have demonstrated, may indeed have importance for the development of the polyneuropathy. These antibodies might reach the target in the peripheral nerve system, at least at nerve root level, without the need for passage from serum through the blood-nerve barrier.

Since MAG is a normal constituent of the central nervous system, there is also the possibility for central nervous system damage as a result of the intrathecal anti-MAG antibody production. This has been supported by experimental studies, such as injection of mammalian optic nerves with a monoclonal anti-MAG antibody together with complement, which indeed produced demyelination.[30] It is, however, not clear if patients with anti-MAG antibodies have some subclinical central nervous system damage in addition to their overt polyneuropathy.

We could demonstrate that the anti-MAG reactivity was within the IgM monoclonal component in the five serum samples and the three CSF specimens that were analyzed. In these patients, the anti-MAG antibodies were

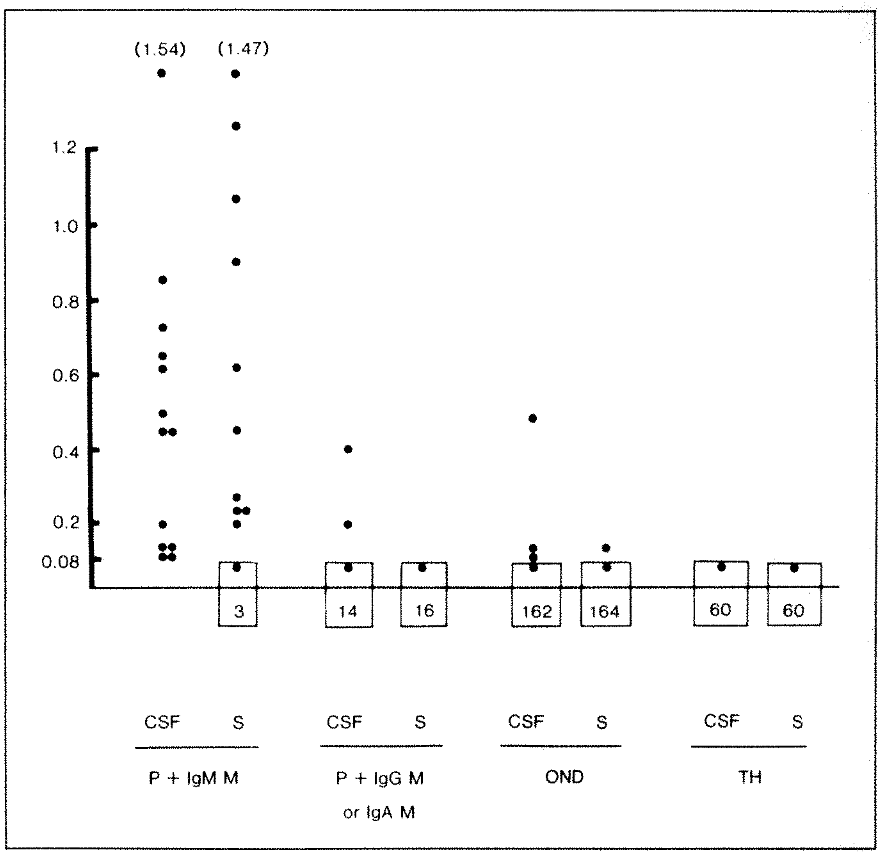

Fig 1.—Anti-myelin-associated glycoprotein (MAG) IgM antibodies determined by enzyme-linked immunosorbent assay in cerebrospinal fluid (CSF) and serum samples (S) from 13 patients with polyneuropathy (P) and IgM monoclonal (M) component, 16 with polyneuropathy and IgG or IgA M component, 165 with other neurologic diseases (OND) and 60 with tension headache (TH). Cut-off limit for CSF is OD = 0.08, and for serum optical/density = 0.11. Numbers in squares correspond to numbers of subjects in each group who had values below these cut-off limits.

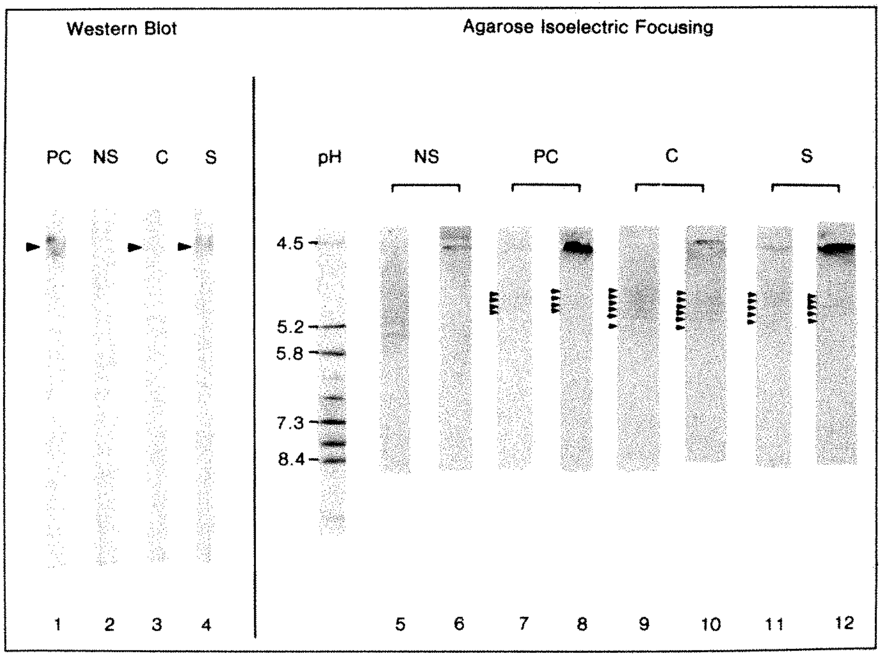

Fig 2.—Demonstration in patient 4 of anti-myelin-associated glycoprotein (MAG) IgM antibody reactivity (arrowheads) in cerebrospinal fluid (CSF) (3) and serum (S) samples (4), using Western blot (to the left). Migration patterns of IgM (arrowheads) on agarose isoelectric focusing in CSF (9) and serum samples (11), and of anti-MAG IgM antibodies detected by immunoblot in CSF (10) and serum samples (12). produced by the neoplastic clone of plasma cells. In those five polyneuropathy patients with monoclonal component, who had anti-MAG IgM antibodies exclusively in CSF as demonstrated by ELISA, not enough CSF was available to analyze the migration properties of the anti-MAG antibodies. It is less likely that the anti-MAG antibodies in these patients belong to the systemic neoplastic plasma cell clones. Furthermore, it seems highly unlikely that a second neoplastic plasma cell clone producing anti-MAG occurs intrathecally. The CSF cell counts and clinical course in these patients did not indicate any central nervous system plasma cell dyscrasia or lymphoma. Mechanisms for induction of anti-MAG antibodies in these patients thus remain unclear. One possibility is that they represent an immune response secondary to nerve damage induced by other means, for example, a T-cell-mediated attack. This explanation could also apply to the anti-MAG IgG antibodies found in serum samples from a few of our patients with polyneuropathy without association with serum monoclonal component, and a few of those with chronic inflammatory demyelinating polyneuropathy (Table 2).

Involvement of MAG in the pathogenesis of multiple sclerosis has been suggested due to the observation of preferential loss of MAG in the periphery of multiple sclerosis plaques.[31-33] Attempts to detect anti-MAG antibodies in CSF and serum samples of patients with multiple sclerosis have given conflicting results,[34-37] probably due to different detection methods used (Möller et al[38]). Our low rate of detection of anti-MAG IgM and IgG antibodies in multiple sclerosis by ELISA is in agreement with previous reports using radioimmunoassay.[35,36,38] It is, however, possible that autoreactive antibodies are bound in vivo to target structures and therefore are difficult to detect in CSF by conventional techniques such as ELISA and radioimmunoassay.

We have demonstrated the regular occurrence of anti-MAG IgM antibodies in CSF from a group of patients with polyneuropathy associated with monoclonal component of IgM isotype. In about half of these patients, there was evidence for intrathecal synthesis of these antibodies.

This study was supported in part by the Swedish Medical Research council and the Swedish Multiple Sclerosis Society.

This study was partly performed at the Clinical Research Center, Huddinge (Sweden) University Hospital.

In Tourette Syndrome ORAP™ (pimozide) Tablets Helps Patients Be Themselves*

- **Excellent Symptom Control**

  "Pimozide produced significantly more improvement of symptoms and less akinesic adverse effects than haloperidol. . . . Improvement of 70% or more was reported by 74% of patients on pimozide compared with 45% on haloperidol ($p < .02$), and 84% rated pimozide better overall than haloperidol."[1]

- **Significantly Less Sedation than Haloperidol**

  In a double-blind, placebo-controlled study, "Pimozide was associated with lethargy or tiredness on significantly fewer days than haloperidol ($p < .01$), and this was reflected in greater immediate and long-term patient acceptance. . . ."[2]

- **Documented Clinical Experience**

  Pimozide has been used in the treatment of Tourette Syndrome for over 10 years.[1]

For more information on ORAP, call 1-800-292-4283.

The Less Sedating Therapy for Tourette Syndrome

* ORAP is indicated for patients who have failed to respond satisfactorily to standard treatment.

ORAP™ The Less Sedating Therapy for Tourette Syndrome

(pimozide) Tablets

INDICATIONS AND USAGE

ORAP (pimozide) is indicated for the suppression of motor and phonic tics in patients with Tourette's Disorder who have failed to respond satisfactorily to standard treatment. ORAP is not intended as a treatment of first choice nor is it intended for the treatment for tics that are merely annoying or cosmetically troublesome. ORAP should be reserved for use in Tourette's Disorder patients whose development and/or daily life function is severely compromised by the presence of motor and phonic tics.

Evidence supporting approval of pimozide for use in Tourette's Disorder was obtained in two controlled clinical investigations which enrolled patients between the ages of 8 and 53 years. Most subjects in the two trials were 12 or older.

CONTRAINDICATIONS

1. ORAP (pimozide) is contraindicated in the treatment of simple tics or tics other than associated withTourette's Disorder.
2. ORAP should not be used in patients taking drugs that may, themselves, cause motor and phonic tics (e.g., pemoline, methylphenidate and amphetamines) until such patients have been withdrawn from these drugs to determine whether or not the drugs, rather than Tourette's Disorder, are responsible for the tics.
3. Because ORAP prolongs the QT interval of the electrocardiogram it is contraindicated in patients with congenital long QT syndrome, patients with a history of cardiac arrhythmias, or patients taking other drugs which prolong the QT interval of the electrocardiogram (see DRUG INTERACTIONS).
4. ORAP is contraindicated in patients with severe toxic central nervous system depression or comatose states from any cause.
5. ORAP is contraindicated in patients with hypersensitivity to it. As it is not known whether cross-sensitivity exists among the antipsychotics, pimozide should be used with appropriate caution in patients who have demonstrated hypersensitivity to other antipsychotic drugs.

WARNINGS

The use of ORAP (pimozide) in the treatment of Tourette's Disorder involves different risk/benefit considerations than when antipsychotic drugs are used to treat other conditions. Consequently, a decision to use ORAP should take into consideration the following: (see also PRECAUTIONS–Information for Patients).

Tardive Dyskinesia A syndrome consisting of potentially irreversible, involuntary, dyskinetic movements may develop in patients treated with antipsychotic drugs. Although the prevalence of the syndrome appears to be highest among the elderly, especially elderly women, it is impossible to rely upon prevalence estimates to predict, at the inception of antipsychotic treatment, which patients are likely to develop the syndrome. Whether antipsychotic drug products differ in their potential to cause tardive dyskinesia is unknown.

Both the risk of developing tardive dyskinesia and the likelihood that it will become irreversible are believed to increase as the duration of treatment is withdrawn. Antipsychotic treatment, itself, however, may suppress (or partially suppress) the signs and symptoms of the syndrome and thereby may possibly mask the underlying process. The effect that symptomatic suppression has upon the long-term course of the syndrome is unknown.

Given these considerations, antipsychotic drugs should be prescribed in a manner that is most likely to minimize the occurrence of tardive dyskinesia. Chronic antipsychotic treatment should generally be reserved for patients who suffer from a chronic illness that, 1) is known to respond to antipsychotic drugs, and, 2) for whom alternative, equally effective, but potentially less harmful treatments are not available or appropriate. In patients who do require chronic treatment, the smallest dose and the shortest duration of treatment producing a satisfactory clinical response should be sought. The need for continued treatment should be reassessed periodically.

If signs and symptoms of tardive dyskinesia appear in a patient on antipsychotics, drug discontinuation should be considered. However, some patients may require treatment despite the presence of the syndrome.

(For further information about the description of tardive dyskinesia and its clinical detection, please refer to ADVERSE REACTIONS and PRECAUTIONS–Information for Patients.)

Neuroleptic Malignant Syndrome (NMS) A potentially fatal symptom complex sometimes referred to as Neuroleptic Malignant Syndrome (NMS) has been reported in association with antipsychotic drugs. Clinical manifestations of NMS are hyperpyrexia, muscle rigidity, altered mental status (including catatonic signs) and evidence of autonomic instability (irregular pulse or blood pressure, tachycardia, diaphoresis, and cardiac dysrhythmias). Additional signs may include elevated creatine phosphokinase, myoglobinuria (rhabdomyolysis) and acute renal failure.

The diagnostic evaluation of patients with this syndrome is complicated. In arriving at a diagnosis, it is important to identify cases where the clinical presentation includes both serious medical illness (e.g., pneumonia, systemic infection, etc.) and untreated or inadequately treated extrapyramidal signs and symptoms (EPS). Other important considerations in the differential diagnosis include central anticholinergic toxicity, heat stroke, drug fever and primary central nervous system (CNS) pathology.

The management of NMS should include 1) immediate discontinuation of antipsychotic drugs and other drugs not essential to concurrent therapy, 2) intensive symptomatic treatment and medical monitoring, and 3) treatment of any concomitant serious medical problems for which specific treatments are available. There is no general agreement about specific pharmacological treatment regimens for uncomplicated NMS.

If a patient requires antipsychotic drug treatment after recovery from NMS, the potential reintroduction of drug therapy should be carefully considered. The patient should be carefully monitored, since recurrences of NMS have been reported.

Hyperpyrexia, not associated with the above symptom complex, has been reported with other antipsychotic drugs.

Other Sudden, unexpected deaths have occurred in experimental studies of conditions other than Tourette's Disorder. These deaths occurred while patients were receiving dosages in the range of 1 mg per kg. One possible mechanism for such deaths is prolongation of the QT interval predisposing patients to ventricular arrhythmia. An electrocardiogram should be performed before ORAP treatment is initiated and periodically thereafter, especially during the period of dose adjustment.

ORAP may have a tumorigenic potential. Based on studies conducted in mice, it is known that pimozide can produce a dose related increase in pituitary tumors. The full significance of this finding is not known, but should be taken into consideration in the physician's and patient's decisions to use this drug product. This finding should be given special consideration when the patient is young and chronic use of pimozide is anticipated. (see PRECAUTIONS–Carcinogenesis, Mutagenesis, Impairment of Fertility).

PRECAUTIONS

General ORAP (pimozide) may impair the mental and/or physical abilities required for the performance of potentially hazardous tasks, such as driving a car or operating machinery, especially during the first few days of therapy.

ORAP produces anticholinergic side effects and should be used with caution in individuals whose conditions may be aggravated by anticholinergic activity.

ORAP should be administered cautiously to patients with impairment of liver or kidney function, because it is metabolized by the liver and excreted by the kidneys.

Antipsychotics should be administered with caution to patients receiving anticonvulsant medication, with a history of seizures, or with EEG abnormalities, because they may lower the convulsive threshold. If indicated, adequate anticonvulsant therapy should be maintained concomitantly.

Laboratory Tests An ECG should be done at baseline and periodically thereafter throughout the period of dose adjustment. Any indication of prolongation of QT_c interval beyond an absolute limit of 0.47 seconds (children) or 0.52 seconds (adults), or more than 25% above the patient's original baseline should be considered a basis for stopping further dose increase (see CONTRAINDICATIONS) and considering a lower dose.

Since hypokalemia has been associated with ventricular arrhythmias, potassium insufficiency, secondary to diuretics, diarrhea, or other cause, should be corrected before ORAP therapy is initiated and normal potassium maintained during therapy.

Drug Interactions Because ORAP prolongs the QT interval of the electrocardiogram, an additive effect on QT interval would be anticipated if administered with other drugs, such as phenothiazines, tricyclic antidepressants or antiarrhythmic agents, which prolong the QT interval. Such concomitant administration should not be undertaken (see CONTRAINDICATIONS).

ORAP may be capable of potentiating CNS depressants, including analgesics, sedatives, anxiolytics, and alcohol.

Carcinogenesis, Mutagenesis, Impairment of Fertility Carcinogenicity studies were conducted in mice and rats. In mice, pimozide causes a dose-related increase in pituitary and mammary tumors.

When mice were treated for up to 18 months with pimozide, pituitary gland changes developed in females only. These changes were characterized as hyperplasia at doses approximating the human dose and adenoma at doses about fifteen times the maximum recommended human dose on a mg per kg basis. The mechanism for the induction of pituitary tumors in mice is not known.

Mammary gland tumors in female mice were also increased, but these tumors are expected in rodents treated with antipsychotic drugs which elevate prolactin levels. Chronic administration of an antipsychotic also causes elevated prolactin levels in humans. Tissue culture experiments indicate that approximately one-third of human breast cancers are prolactin-dependent in vitro, a factor of potential importance if the prescription of these drugs is contemplated in a patient with a previously detected breast cancer. Although disturbances such as galactorrhea, amenorrhea, gynecomastia, and impotence have been reported with antipsychotic drugs, the clinical significance of elevated serum prolactin levels is unknown for most patients. Neither clinical studies nor epidemiologic studies conducted to date have shown an association between chronic administration of these drugs and mammary tumorigenesis. The available evidence, however, is considered too limited to be conclusive at this time.

In a 24 month carcinogenicity study in rats, animals received up to 50 times the maximum recommended human dose. No increased incidence of overall tumors or tumors at any site was observed in either sex. Because of the limited number of animals surviving this study, the meaning of these results is unclear.

Pimozide did not have mutagenic activity in the Ames test with four bacterial test strains, in the mouse dominant lethal test or in the micronucleus test in rats.

Reproduction studies in animals were not adequate to assess all aspects of fertility. Nevertheless, female rats administered pimozide had prolonged estrus cycles, an effect also produced by other antipsychotic drugs.

Pregnancy Category C. Reproduction studies performed in rats and rabbits at oral doses up to 8 times the maximum human dose did not reveal evidence of teratogenicity. In the rat, however, this multiple of the human dose resulted in decreased pregnancies and in the retarded development of fetuses. These effects are thought to be due to an inhibition or delay in implantation which is also observed in rodents administered other antipsychotic drugs. In the rabbit, maternal toxicity, mortality, decreased weight gain, and embryotoxicity including increased resorptions were dose related. Because animal reproduction studies are not always predictive of human response, pimozide should be given to a pregnant woman only if the potential benefits of treatment clearly outweigh the potential risks.

Labor and Delivery This drug has no recognized use in labor or delivery.

Nursing Mothers It is not known whether pimozide is excreted in human milk. Because many drugs are excreted in human milk and because of the potential for tumorigenicity and unknown cardiovascular effects in the infant, a decision should be made whether to discontinue nursing or to discontinue the drug, taking into account the importance of the drug to the mother.

Pediatric Use Although Tourette's Disorder most often has its onset between the ages of 2 and 15 years, information on the use and efficacy of ORAP in patients less than 12 years of age is limited.

Because its use and safety have not been evaluated in other childhood disorders, ORAP is not recommended for use in any condition other than Tourette's Disorder.

ADVERSE REACTIONS

General Extrapyramidal Reactions: Neuromuscular (extrapyramidal) reactions during the administration of ORAP (pimozide) have been reported frequently, often during the first few days of treatment. In most patients, these reactions involved Parkinson-like symptoms which, when first observed, were usually mild to moderately severe and usually reversible.

Other types of neuromuscular reactions (motor restlessness, dystonia, akathisia, hyperreflexia, opisthotonos, oculogyric crises) have been reported far less frequently. Severe extrapyramidal reactions have been reported to occur at relatively low doses. Generally the occurrence and severity of most extrapyramidal symptoms are dose related since they occur at relatively high doses and have been shown to disappear or become less severe when the dose is reduced. Administration of antiparkinson drugs such as benztropine mesylate or trihexyphenidyl hydrochloride may be required for control of such reactions. It should be noted that persistent extrapyramidal reactions have been reported and that the drug may have to be discontinued in such cases.

Withdrawal Emergent Neurological Signs: Generally, patients receiving short term therapy experience no problems with abrupt discontinuation of antipsychotic drugs. However, some patients on maintenance treatment experience transient dyskinetic signs after abrupt withdrawal. In certain of these cases the dyskinetic movements are indistinguishable from the syndrome described below under 'Tardive Dyskinesia' except for duration. It is not known whether gradual withdrawal of antipsychotic drugs will reduce the rate of occurrence of withdrawal emergent neurological signs but until further evidence becomes available, it seems reasonable to gradually withdraw use of ORAP.

Tardive Dyskinesia: ORAP may be associated with persistent dyskinesias. Tardive dyskinesia, a syndrome consisting of potentially irreversible, involuntary, dyskinetic movements, may appear in some patients on long-term therapy or may occur after drug therapy has been discontinued. The risk appears to be greater in elderly patients on high-dose therapy, especially females. The symptoms are persistent and in some patients appear irreversible. The syndrome is characterized by rhythmical involuntary movements of tongue, face, mouth or jaw (e.g., protrusion of tongue, puffing of cheeks, puckering of mouth, chewing movements). Sometimes these may be accompanied by involuntary movements of extremities and the trunk.

There is no known effective treatment for tardive dyskinesia; antiparkinson agents usually do not alleviate the symptoms of this syndrome. It is suggested that all antipsychotic agents be discontinued if these symptoms appear. Should it be necessary to reinstitute treatment, or increase the dosage of the agent, or switch to a different antipsychotic agent, this syndrome may be masked.

It has been reported that fine vermicular movement of the tongue may be an early sign of tardive dyskinesia and if the medication is stopped at that time the syndrome may not develop.

Electrocardiographic Changes. Electrocardiographic changes have been observed in clinical trials of ORAP in Tourette's Disorder and schizophrenia. These have included prolongation of the QT interval, flattening, notching and inversion of the T wave and the appearance of U waves. Sudden, unexpected deaths and grand mal seizure have occurred at doses above 20 mg/day.

Neuroleptic Malignant Syndrome: Neuroleptic malignant syndrome (NMS) has been reported with ORAP. (See WARNINGS for further information concerning NMS.)

Hyperpyrexia: Hyperpyrexia has been reported with other antipsychotic drugs.

Clinical Trials The following adverse reaction tabulation was derived from 20 patients in a 6 week long placebo controlled clinical trial of ORAP in Tourette's Disorder.

Body System/ Adverse Reaction	Pimozide (N = 20)	Placebo (N = 20)
Body as a Whole		
Headache	1	2
Gastrointestinal		
Dry mouth	5	1
Diarrhea	1	0
Nausea	0	2
Vomiting	0	1
Constipation	4	2
Eructations	0	1
Thirsty	1	0
Appetite increase	1	0
Endocrine		
Menstrual disorder	0	1
Breast secretions	0	1
Musculoskeletal		
Muscle cramps	0	1
Muscle tightness	3	0
Stooped posture	2	0
CNS		
Drowsiness	7	3
Sedation	14	5
Insomnia	2	2
Dizziness	0	1
Akathisia	8	0
Rigidity	2	0
Speech disorder	2	0
Handwriting change	1	0
Akinesia	8	0
Psychiatric		
Depression	2	3
Excitement	0	1
Nervous	1	0
Adverse behavior effect	5	0
Special Sense		
Visual disturbance	4	0
Taste change	1	0
Sensitivity of eyes to light	1	0
Decreased accommodation	4	1
Spots before eyes	0	1
Urogenital		
Impotence	3	0

Because clinical investigational experience with ORAP in Tourette's Disorder is limited, uncommon adverse reactions may not have been detected. The physician should consider that other adverse reactions associated with antipsychotics may occur.

Other Adverse Reactions In addition to the adverse reactions listed above, those listed below have been reported in U.S. clinical trials of ORAP in conditions other than Tourette's Disorder.

Body as a Whole. Asthenia, chest pain, periorbital edema

Cardiovascular/Respiratory. Postural hypotension, hypotension, hypertension, tachycardia, palpitations

Gastrointestinal. Increased salivation, nausea, vomiting, anorexia, GI distress

Endocrine: Loss of libido

Metabolic/Nutritional: Weight gain, weight loss

Central Nervous System: Dizziness, tremor, parkinsonism, fainting, dyskinesia

Psychiatric. Excitement

Skin: Rash, sweating, skin irritation

Special Senses: Blurred vision, cataracts

Urogenital. Noctura, urinary frequency

Postmarketing Reports The following experiences were described in spontaneous postmarketing reports. These reports do not provide sufficient information to establish a clear causal relationship with the use of ORAP.

Hematologic: Hemolytic anemia

OVERDOSAGE

In general, the signs and symptoms of overdosage with ORAP (pimozide) would be an exaggeration of known pharmacologic effects and adverse reactions, the most prominent of which would be: 1) electrocardiographic abnormalities, 2) severe extrapyramidal reactions, 3) hypotension, 4) a comatose state with respiratory depression.

In the event of overdosage, gastric lavage, establishment of a patent airway and, if necessary mechanically-assisted respiration are advised. Electrocardiographic monitoring should commence immediately and continue until the ECG parameters are within the normal range. Hypotension and circulatory collapse may be counteracted by use of intravenous fluids, plasma, or concentrated albumin, and vasopressor agents such as metaraminol, phenylephrine and norepinephrine. Epinephrine should not be used. In case of severe extrapyramidal reactions, antiparkinson medication should be administered. Because of the long half-life of pimozide, patients who take an overdose should be observed for at least 4 days. As with all drugs, the physician should consider contacting a poison control center for additional information on the treatment of overdose.

DOSAGE AND ADMINISTRATION

Reliable dose response data for the effects of ORAP (pimozide) on tic manifestations in Tourette's Disorder patients below the age of twelve are not available. Consequently, the suppression of tics by ORAP requires a slow and gradual introduction of the drug. The patient's dose should be carefully adjusted to a point where the suppression of tics and the relief afforded is balanced against the untoward side effects of the drug.

An ECG should be done at baseline and periodically thereafter, especially during the period of dose adjustment (see WARNINGS and PRECAUTIONS–Laboratory Tests).

In general, treatment with ORAP should be initiated with a dose of 1 to 2 mg a day in divided doses. The dose may be increased thereafter every other day. Most patients are maintained at less than 0.2 mg/kg per day, or 10 mg/day, whichever is less. Doses greater than 0.2 mg/kg/day or 10 mg/day are not recommended.

Periodic attempts should be made to reduce the dosage of ORAP to see whether or not tics persist at the level and extent first identified. In attempts to reduce the dosage of ORAP, consideration should be given to the possibility that increases of tic intensity and frequency may represent a transient, withdrawal related phenomenon rather than a return of disease symptoms. Specifically, one to two weeks should be allowed to elapse before one concludes that an increase in tic manifestations is a function of the underlying disease syndrome rather than a response to drug withdrawal. A gradual withdrawal is recommended in any case.

HOW SUPPLIED

ORAP (pimozide) 2 mg tablets, white, scored, imprint "LEMMON" and "ORAP-2"—NDC 57844-187-01, bottles of 100.

Dispense in tight, light-resistant containers as defined in the official compendium.

On Drawing Impairment in Alzheimer's Disease

Andrew Kirk, MD, Andrew Kertesz, MD

• Spontaneous drawings of 38 patients, diagnosed by the National Institute of Neurological Disorders and Stroke–Alzheimer's Disease and Related Disorders Association criteria as "probable Alzheimer's disease," and of 39 normal control subjects were analyzed by two independent observers using a standardized scoring system. Drawings of patients with Alzheimer's disease displayed fewer angles, impaired perspective and spatial relations, simplification, and overall impairment compared with those of the control subjects. This represents a combination of the deficits seen following right- *and* left-hemisphere lesions. Neglect, tremor, and perseveration were not prominent. Drawing impairment was relatively independent of language or memory impairment, but drawing performance was related to perceptual *and* executive dysfunction in the visuospatial domain. Deterioration was followed up for up to 3 years.

(*Arch Neurol.* 1991;48:73-77)

Deficits in constructional abilities, including drawing, are often early signs of degenerative dementia.[1-3] The importance of investigating these aspects of dementia has been brought out by Henderson et al,[4] who demonstrated that patients with Alzheimer's disease (AD) who perform poorly on drawing tasks more often wander and become lost, making their management difficult and predisposing them to complications.[5] Despite the obvious clinical relevance of constructional ability and despite a sizable body of literature contrasting the characteristics of drawing impairment after right- and left-hemisphere damage,[6-22] comparatively little is known about how dementia affects constructional performance.

Following Kleist's[23] 1922 work on "constructional apraxia," there were some early descriptions of constructional disability in dementia, notably by Lhermitte and Trelles[24] and by Mayer-Gross.[25] In retrospect, most of the latter's cases probably represented multi-infarct dementia. Gainotti[26] confirmed and refined Mayer-Gross's[25] observations on *closing-in*—a tendency (uncommon in those with unilateral cerebral damage) for demented patients to draw directly on the model in copying tasks.

Benton and Fogel[27] documented a high incidence of constructional disability in patients with unspecified "diffuse or bilateral lesions," compared with control subjects and with subjects with single lesions. Villa et al[28] contended that coexistent mental deterioration is an important determinant of the degree of constructional disability in patients with unilateral lesions. The relevance of these results to AD is uncertain, especially in light of the demonstration, in a small number of patients with AD, that drawing may be more impaired in those with positron emission tomographic evidence of more marked right than left parietal hypometabolism.[29] It is thus unclear whether drawing disability in AD is a result of widespread cerebral dysfunction or is instead due to damage to specific cortical areas.

Since Paterson and Zangwill's[30] pioneering 1944 investigation, several authors[7,9,13,22,31-33] have confirmed that, despite tremendous variability, the drawings of patients with right-brain damage (RBD) tend to display hemispatial neglect and a piecemeal approach in which individual details may be represented well but are not placed in accurate spatial relationship with one another. On the other hand, patients with left-brain damage (LBD) produce simplified, tremulous drawings with fewer angles.[7-9,13,22,32,33] On the basis of such qualitative differences, Duensing,[34] Piercy et al,[6] and McFie and Zangwill[35] developed the hypothesis that RBD drawing disability is due to a visuoperceptual deficit, while LBD drawings are impaired by an executive defect. This formulation has not been borne out by later investigators,[7,36,37] who found that patients with constructional disability performed more poorly on visuoperceptual tests than did those without constructional disability, no matter which hemisphere was damaged. Detailed investigations along these lines have not, to our knowledge, been carried out in AD. It is not clear whether patients with AD make typical RBD errors, LBD errors, both, or neither. The roles of perceptual vs executive deficits in AD construction also remain to be elucidated.

Drawing is known to worsen as AD progresses,[1,38] but the relationship between deterioration of construction and of other cognitive functions, such as language and memory, has important implications with respect to how cognition is impaired in AD. *Stage* models of AD propose simultaneous and homogeneous deterioration of disparate functions as the disease progresses[39,40]; on the other hand, *subgroup* models postulate separate populations of patients characterized by predominance of one or another type of symptom, especially early in the illness.[41] As drawing impairment parallels impairment of comprehension in patients with LBD,[14,16,22] the interaction between drawing and aphasia is particularly important.

Using a standardized rating system, previously demonstrated to be an effective instrument in the study of drawing after focal cerebral damage,[22]

we compared the spontaneous drawings of patients with probable AD with those of control subjects to determine how drawing is affected by AD. Retesting examined drawing deterioration with disease progression. Through concomitant testing of other neuropsychologic functions, we explored the relationships between drawing, memory, language, and visuoperceptual function in AD. Using computed tomography and magnetic resonance imaging, we hoped to ensure a more homogeneous group of patients than were included in studies of drawing in dementia from the pre-computed tomography era.[25,26]

Table 1.—Criteria Used to Rate Drawings*

Items Rated on 0-3 Scale

Scale
  0, normal
  1, mildly abnormal
  2, moderately abnormal
  3, severely abnormal
Overlap
  Tendency for separate drawings to be superimposed (single rating for all drawings)
Spatial relationships
  Tendency for components of drawings to be put together abnormally with respect to one another in a piecemeal fashion, so that the whole picture is distorted, resembling an "exploded diagram"
Simplification
  Tendency to oversimplify the drawing, leaving out details
Angle production
  Difficulty forming angles with a tendency to represent them as gaps, scrawls, or curved lines (circle not rated)
Perseveration
  Tendency to redraw lines, parts of the drawing, or the entire drawing
Tremor
  Tendency for lines to be shaky
Perspective
  Tendency for three-dimensional perspective to be poorly represented (only cube, house, and person rated)
Overall impairment
  Rating of each drawing as a whole.

Items Rated on −3 to +3 Scale

Scoring system as above but with negative numbers indicating leftward error and positive rightward
Orientation
  Tendency for drawings to be placed diagonally on the page. Sign indicates the side away from which the drawing leans (circle not rated)
Neglect
  Tendency for one side of the drawing to be incomplete or underdeveloped
Displacement
  Tendency for drawings to be displaced toward one side of the page (single rating for all drawings)

Items Counted

Details
  Total No. of details included (eg, numbers, hands, windows, facial features)
Details externalized
  No. of details incorrectly placed outside rather than inside the outline of the drawing (circle and square not rated)
Angles
  Total No. of angles drawn and percentage acute, right, and obtuse (clock, tree, and person not rated)
Redrawn lines
  No. of lines that have been overdrawn at least once
Line production
  Total No. of lines drawn (only circle, square, and cube rated)
Line joining
  No. of gaps separating lines that should meet
Line crossing
  No. of crossings of lines that should just meet
Extras
  No. of items spontaneously drawn in addition to those requested (single rating for all drawings)

*From Kirk and Kertesz.[22]

PATIENTS AND METHODS

Patients

Thirty-eight patients diagnosed as "probable AD,"[42] according to the National Institute of Neurological Disorders and Stroke-Alzheimer's Disease and Related Disorders Association criteria and 39 normal control subjects were included in our study. Because of the documented importance of impaired comprehension in drawing disability,[14,16,22] we were careful not to exclude subjects with AD on the basis of aphasia. Exclusions were made only if there was diagnostic uncertainty after complete neurologic and laboratory assessment, or if there was a history of stepwise progression, stroke, or other neurologic disease. Control subjects were patients' spouses, hospital employees, and other volunteers without history of neurologic disease or of any other illness likely to impair drawing (eg, substantial arthritis). Control subjects were required to score above 124 on the Mattis Dementia Rating Scale.[43] The two groups did not significantly differ in age (AD: 70.0 years, SD, 9.3; control: 65.9 years, SD, 8.5; $P > .05$) or educational attainment (AD: 11.1 years, SD, 4.1; control: 11.9 years, SD, 2.8; $P > .3$).

Procedure

The Western Aphasia Battery (WAB),[44] Raven's Coloured Progressive Matrices,[45] Wechsler Adult Intelligence Scale-Revised,[46] Wechsler Memory Scale,[47] and Dementia Rating Scale[43] were administered to all patients with AD at the time of their initial referral by a neurologist for neuropsychologic assessment (test 1). The WAB drawing subtest was administered by asking each patient to draw spontaneously (not copy) a circle, cube, square, clock, tree, house, and person, after being shown a sample drawing for 10 seconds, as specified in the WAB instructions. Control subjects performed the same subtest. As part of an ongoing study, patients with AD have been retested at yearly intervals, wherever possible. Retesting always includes the WAB. Twenty-seven patients have been retested at 1 year, 14 of those at 2 years, and six again at 3 years. Disease duration at the time of initial testing was estimated by history from the patient, his family, and his medical record. All patients with AD underwent computed tomographic and 26 also underwent magnetic resonance imaging scans.

Each set of seven drawings from a single WAB session was assigned a random number and identifying data were masked. Drawings were then scored independently by two raters (one a physician, one with no training in medicine or psychology) who did not know whether a given drawing had been produced by a patient with AD or by a control subject or whether a drawing resulted from an initial assessment or from a retest. Raters analyzed drawings according to the criteria shown in Table 1; each drawing was rated individually unless otherwise stated. High interobserver agreement has previously been demonstrated for this scoring system.[22] For each item in Table 1, scores from the seven individual drawings were added to give a series of total item scores for each testing session. The mean of the two raters' scores became each subject's final score for each item for each testing session. Reliability of the ratings (as assessed by Pearson Product-Moment correlation coefficients between the two raters' scores for each item in Table 1, corrected by the Spearman-Brown formula, since final scores were means of two raters' scores) was acceptable. The mean reliability coefficient for the items in Table 1 was 0.79.

Because multiple comparisons were performed, $P < .005$ was used as a conservative criterion of significance for each statistical comparison.

RESULTS

At test 1, in the patients with AD, mean disease duration was 29.0 months (SD, 18.1). Their mean WAB aphasia quotient was 86.0 (SD, 10.8); Wechsler Adult Intelligence Scale-Re-

Perspective	2.17 (1.82)	3.80 (1.93)	<.0005
Simplification	1.77 (1.68)	4.58 (4.22)	<.0005
Overall impairment	5.20 (3.25)	9.34 (4.49)	<.0005

*NS indicates not significant.

vised verbal IQ, 83.5 (SD, 12.6); performance IQ, 79.7 (SD, 13.4); full scale IQ, 81.0 (SD, 12.7); Dementia Rating Scale total score, 99.6 (SD, 20.0); and Wechsler Memory Scale memory quotient, 75.4 (SD, 14.6). Table 2 summarizes subjects' drawing scores. It can be seen that patients with AD included significantly fewer angles and that they showed more impairment of perspective and spatial relations, more simplification, and more overall impairment.

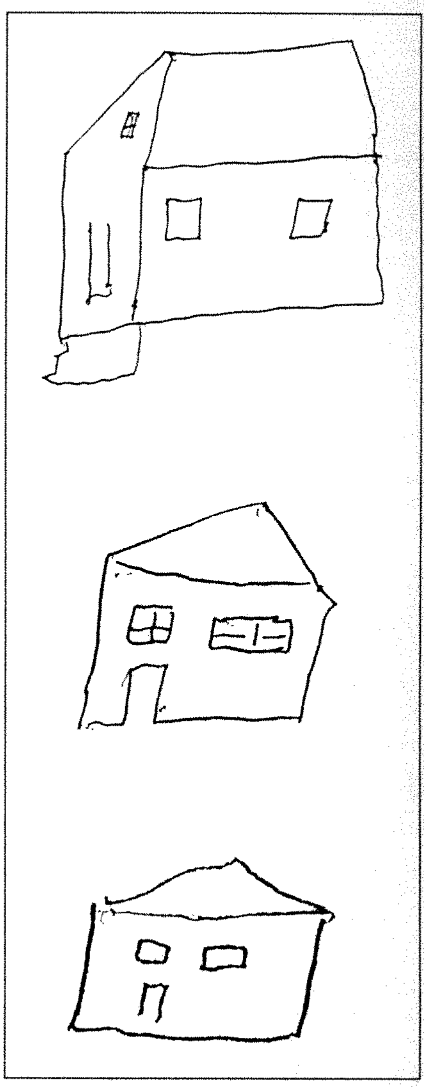
The Pearson Product-Moment correlation coefficients between overall drawing impairment and each of the WAB language scores (information content, fluency, comprehension, repetition, naming, and aphasia quotient) were all nonsignificant. There were also no significant correlations between overall drawing impairment and any of the Wechsler Memory Scale memory scores, including memory quotient. The WAB subtests significantly correlated with overall drawing impairment were reading ($r = -.64$; $P < .001$), writing ($r = -.62$; $P < .001$), and praxis ($r = -.50$; $P < .001$). The significant correlations of drawing impairment with Wechsler Adult Intelligence Scale-Revised IQs or subtest scores were with arithmetic ($r = -.58$; $P < .001$), picture arrangement ($r = -.59$; $P < .001$), block design ($r = -.64$; $P < .001$), and object assembly ($r = -.67$; $P < .001$). The only Dementia Rating Scale score significantly correlated with drawing impairment was construction ($r = -.53$; $P < .001$). Overall drawing impairment also correlated significantly with score on Raven's Coloured Progressive Matrices ($r = -.59$; $P < .001$).

Table 3.—Pearson Product-Moment Correlation Coefficients (*r*) Between Drawing Scores and Disease Duration Since Initial Testing

	r	*P*
Spatial relations	.20	>.1
Perspective	−.27	<.01
Simplification	−.30	<.01
Overall impairment	−.32	<.01
Total No. of angles	−.43	<.001

None of the drawing scores of either patients with AD or control subjects were significantly correlated with age.

To study how drawing deteriorates as AD progresses, we examined the correlations between the significantly impaired drawing item scores from Table 1 (simplification, perspective, total number of angles, spatial relations, and overall impairment) and disease duration since the first test. These retest results are shown in Table 3 and a typical example of drawing deterioration over three yearly tests is shown in the Figure.



Top, Drawing of a house by a 69-year-old woman with probable Alzheimer's disease of 2 years' estimated duration. Note poor perspective and mild difficulty with spatial relations between components. Middle, Drawing by same patient, 1 year later. Note simplification and lack of perspective. Bottom, Drawing by same patient, disease duration now 4 years. Note further simplification.

COMMENT

Table 2 shows that drawings of patients with AD are worse than drawings of control subjects in several respects. Simplification and a reduced number of angles (without alteration in the proportions of each type of angle) are characteristics shared between patients with AD and patients with LBD.[22] Impairment of spatial relations, also found in drawings of patients with AD, is a fundamental RBD deficit.[7,9,13,22,31-33] Impaired perspective is a fault shared by AD, LBD, and RBD.[22] Thus, drawings of patients with AD appear to be affected by deficiencies typical of both left- *and* right-hemisphere damage. There are some important, and not unanticipated, exceptions to this general rule. Constructions by patients with AD do not display the hemispatial neglect typical of RBD drawings. This finding is consistent with the usual bilateral and insidious nature of AD. Neglect generally recovers substantially after acute unilateral lesions and is unusual in degenerative diseases, even those, such as hemiparkinsonism, in which structures important in attention may be affected asymmetrically.[48-50] Lack of neglect in AD drawing attests to the brain's ability to compensate for slowly progressive damage to attention and intention systems, and particularly to the relative symmetry of the disease in question.

Unlike LBD drawings, AD drawings are not more tremulous than control subjects' drawings. However, LBD tremulousness is a feature closely linked to severity of right hemiparesis,[22] not a characteristic of AD.

Perseveration has been found to be a deficit common to both LBD and RBD drawings[22] but is not seen in the current series of patients with AD. Although perseveration is considered common in AD,[51] there are several potential explanations for our result. First, the overwhelming tendency of patients with AD to simplify their drawings may outweigh any propensity to perseverate. Second, it is verbal rather than nonverbal perseveration that has been found to be most typical of AD.[52,53] Third, even verbal perseverations are an infrequent phenomenon in the individual patient[52] and our brief drawing test may not have been extensive enough to bring out instances of perseverative behavior. Finally, because of the nature of the task, our techniques are more sensitive to *recurrent*, than to *stuck-in-set* or *continuous* perseveration,[51,54] which could potentially occur independently in the nonverbal behavior of patients with AD or at different times in disease progression.

It should be borne in mind that test 1 represents the first neuropsychologic assessment of the patients with AD. Thus, this group with early AD is likely to show less drawing impairment than would a group of patients with advanced disease.

Although some previous data[27] seem to suggest that drawing is worse with diffuse than with unilateral disease, direct quantitative comparison of drawing deficit severity between AD, RBD, and LBD would provide little useful information. Lesion size, useful in ensuring uniformity between LBD and RBD, is meaningless as a control in AD as drawing quality depends on the advance of the disease.

We found overall drawing impairment related to performance in several other areas. The Dementia Rating Scale construction, Wechsler Adult Intelligence Scale-Revised picture arrangement, block design, and object assembly clearly share with drawing underlying cognitive and motor processes in the visuospatial domain. Reading and Raven's Coloured Progressive Matrices, both of which require considerable visuoperceptual ability; writing, which makes demands on graphomotor executive function; and praxis, another executive ability, are all significantly correlated with the degree of drawing impairment in AD. This relationship with both perceptual and executive abilities implies that drawing disability in patients with AD, displaying characteristics typical of both RBD and LBD drawing, may reflect the presence of both a receptive and an executive visuospatial deficit (or dysfunction of a more basic cognitive mechanism common to both processes). To some extent a bitemporoparietal disease, AD is a disorder eminently capable of damaging both components of this dichotomy proposed by Duensing.[34]

Of even more interest than the significant correlations between drawing impairment and certain cognitive functions is the absence of a strong relationship between drawing and language or memory. Previous investigations of these interrelationships have proven inconclusive. Huff et al[55] described significant association between an overall constructional score and memory and language scores in AD. Henderson et al[4] found a significant relationship between drawing and naming but not between drawing and memory. On the other hand, Morris et al[56] identified, through factor analysis, three principal components explaining much of the variation in neuropsychological test performance in AD. These three factors, memory, language, and constructional performance, correspond to the three dissociated abilities in our study. Martin et al[39] found strong relationships between various constructional tasks and between various verbal tasks but little correlation across these groups. They used their finding of two distinct patterns of AD deficit as support for a *subgroup* rather than for a *stage* model for AD. Although our results must be interpreted in the light of this conflicting literature, they would also be more compatible with a subgroup model of AD. According to such a model, construction, language, and memory would be relatively distinct cognitive abilities, deficits of which coexist but do not necessarily develop in parallel in this degenerative disease. Stage and subgroup models are not mutually exclusive. It may be that specific abilities can be impaired relatively selectively early in the illness but that once a critical point is reached, global cognitive impairment must ensue.[41] It is worth noting that, in accord with this idea, the mean estimated disease duration is longer (63 months) in the study of Henderson et al,[4] which is more in keeping with a stage model, than in any of the cited investigations compatible with a subgroup model (52 months in the study of Morris et al[56]; 41 months in that of Martin et al[39]; 29 months in this study). Unfortunately, no estimate of duration is given in the study of Huff et al[55] supporting a stage model. Longitudinal studies, beginning early in the illness, and specifically addressed to these issues are likely to prove most fruitful in clarifying the temporal roles of these two models in AD.

From Table 3, it can be seen that, although AD drawing deficits worsen with time, the correlations are, for the most part, modest. Longitudinal behavioral studies of dementia[57,58] have described much variability in the rapidity of cognitive decline in AD, with deterioration occurring over several years. It is likely that more patients must be followed up longer than in our study to display more dramatic deteriorations in drawing quality.

Drawings of patients with AD display a combination of the deficits seen in both right- and left-hemisphere disease and our data suggest that both a perceptual and an executive visuospatial deficit are present. Severity of drawing impairment is relatively independent of severity of amnesia or language deficit.

Cognitive models of drawing, which may explain the associations and dissociations seen in patients with dementia and in those with focal lesions, need to be explored[59,60] and are likely to increase our understanding of the processes underlying normal drawing.

Dr Kirk was the recipient of a Canadian Heart and Stroke Foundation Research Fellowship. This work was also supported, in part, by PSI grant No. 88-15 to Dr Kertesz.

We thank Linda Carter for her invaluable assistance in the preparation of the manuscript.

Reduces levodopa/ carbidopa dosage — *usually by 10–30%[2,4†]*

Favorable safety profile — *lowering levodopa/carbidopa dose reduces side effects[2,3]*

Selectively inhibits MAO-B *to conserve endogenous and exogenous dopamine[1-3]*

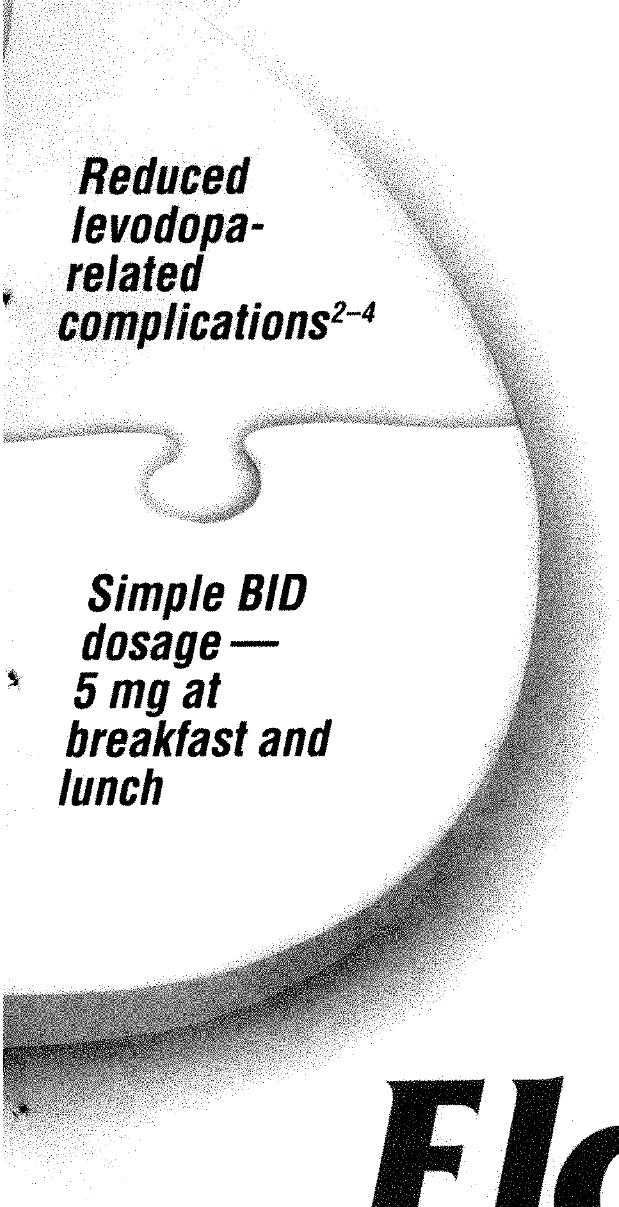
Stabilizes the clinical course — *71% of patients improved[3]*

Improved walking, dressing; reduced drooling and tremor[2]

No tyramine ("cheese") effect *at recommended dosages**

© 1991 Sandoz Pharmaceuticals Corporation/Somerset Pharmaceuticals, Inc.

ELD-1190-01 1/91



Reduced levodopa-related complications[2-4]
Simple BID dosage — 5 mg at breakfast and lunch

Management of Parkinson's disease...
still a puzzle

Benefits that provide a fitting solution

Eldepryl®

(SELEGILINE HYDROCHLORIDE)

Fits your therapeutic strategy

*Higher doses have not been shown to increase benefit and have increased the risk of side effects. Please see Dosage and Administration section of prescribing information.

†Further reduction of levodopa/carbidopa may be possible during continued selegiline therapy.

See next page for brief summary of prescribing information.

Eldepryl®

(SELEGILINE HYDROCHLORIDE)

BRIEF SUMMARY

CLINICAL PHARMACOLOGY:

The mechanisms accounting for selegiline's beneficial adjunctive action in the treatment of Parkinson's disease are not fully understood. Inhibition of monoamine oxidase, type B, activity is generally considered to be of primary importance; in addition, there is evidence that selegiline may act through other mechanisms to increase dopaminergic activity.

INDICATIONS AND USAGE:

ELDEPRYL® (SELEGILINE HYDROCHLORIDE) is indicated as an adjunct in the management of Parkinsonian patients being treated with levodopa/carbidopa who exhibit deterioration in the quality of their response to this therapy. There is no evidence from controlled studies that selegiline has any beneficial effect in the absence of concurrent levodopa therapy.

Evidence supporting this claim was obtained in randomized controlled clinical investigations that compared the effects of added selegiline or placebo in patients receiving levodopa/carbidopa. Selegiline was significantly superior to placebo on all three principal outcome measures employed: change from baseline in daily levodopa/carbidopa dose, the amount of 'off' time, and patient self-rating of treatment success. Beneficial effects were also observed on other measures of treatment success (e.g., measures of reduced end of dose akinesia, decreased tremor and sialorrhea, improved speech and dressing ability and improved overall disability as assessed by walking and comparison to previous state).

CONTRAINDICATIONS:

ELDEPRYL® (SELEGILINE HYDROCHLORIDE) is contraindicated in patients with a known hypersensitivity to this drug.

WARNINGS:

Selegiline should not be used at daily doses exceeding those recommended (10 mg/day) because of the risks associated with non-selective inhibition of MAO. (See CLINICAL PHARMACOLOGY.)

The selectivity of selegiline for MAO B may not be absolute even at the recommended daily dose of 10 mg a day and selectivity is further diminished with increasing daily doses. The precise dose at which selegiline becomes a non-selective inhibitor of all MAO is unknown, but may be in the range of 30 to 40 mg a day.

Because of reports of fatal interactions, MAOIs are ordinarily contraindicated for use with meperidine (DEMEROL & other tradenames). This warning is often extended to other opioids. Because the mechanism of interaction between MAOIs and meperidine is unknown, it seems prudent, in general, to avoid this combination.

Definitive clinical data on the concomitant use of ELDEPRYL® (SELEGILINE HYDROCHLORIDE) and fluoxetine hydrochloride (PROZAC) is not available. Death has been reported to occur following the initiation of therapy with nonselective MAOI's (NARDIL, PARNATE) shortly after discontinuation of fluoxetine. To date, this reaction has not been reported with ELDEPRYL® (SELEGILINE HYDROCHLORIDE), however, since the mechanism of this reaction is not fully understood it seems prudent, in general, to avoid this combination. Because of the long half-lives of fluoxetine and its active metabolite, at least five weeks (approximately 5 half-lives) should elapse beweeen discontinuation of fluoxetine and initiation of MAOI therapy. Based on experience with the combined use of MAOI's and tricyclic antidepressants, at least 14 days should elapse between discontinuation of an MAOI and initiation of treatment with fluoxetine.

PRECAUTIONS:

General: Some patients given selegiline may experience an exacerbation of levodopa associated side effects, presumably due to the increased amounts of dopamine reacting with super-sensitive post-synaptic receptors. These effects may often be mitigated by reducing the dose of levodopa/carbidopa by approximately 10 to 30%.

The decision to prescribe selegiline should take into consideration that the MAO system of enzymes is complex and incompletely understood and there is only a limited amount of carefully documented clinical experience with selegiline. Consequently, the full spectrum of possible responses to selegiline may not have been observed in pre-marketing evaluation of the drug. It is advisable, therefore, to observe patients closely for atypical responses.

Information for Patients: Patients should be advised of the possible need to reduce levodopa dosage after the initiation of ELDEPRYL® (SELEGILINE HYDROCHLORIDE) therapy.

Patients (or their families if the patient is incompetent) should be advised not to exceed the daily recommended dose of 10 mg. The risk of using higher daily doses of selegiline should be explained, and a brief description of the 'cheese reaction' provided. While hypertensive reactions with selegiline have not been reported, documented experience is limited. Consequently, it may be useful to inform patients (or their families) about the signs and symptoms associated with MAOI induced hypertensive reactions. In particular, patients should be urged to report, immediately, any severe headache or other atypical or unusual symptoms not previously experienced.

Laboratory Tests: No specific laboratory tests are deemed essential for the management of patients on ELDEPRYL® (SELEGILINE HYDROCHLORIDE). Periodic routine evaluation of all patients, however, is appropriate.

Drug Interactions: No interactions attributed to the combined use of selegiline and other drugs have been reported. However, because the database of documented clinical experience is limited, the level of reassurance provided by this lack of adverse reporting is uncertain. (See WARNINGS and PRECAUTIONS.)

Carcinogenesis, Mutagenesis, and Impairment of Fertility: Studies have not been performed to date to evaluate the carcinogenic potential of selegiline hydrochloride.

Pregnancy: *Pregnancy Category C.* Insufficient animal reproduction studies have been done with selegiline to conclude that selegiline poses no teratogenic risk. However, one rat study carried out at doses as much as 180 fold the recommended human dose revealed no evidence of a teratogenic effect. It is not known whether selegiline can cause fetal harm when administered to a pregnant woman or can affect reproduction capacity. Selegiline should be given to a pregnant woman only if clearly needed.

Nursing Mothers: It is not known whether selegiline hydrochloride is excreted in human milk. Because many drugs are excreted in human milk, consideration should be given to discontinuing the use of all but absolutely essential drug treatments in nursing women.

Pediatric Use: The effects of selegiline hydrochloride in children have not been evaluated.

ADVERSE REACTIONS:

Introduction: The number of patients who received selegiline in prospectively monitored pre-marketing studies is limited. While other sources of information about the use of selegiline are available (e.g., literature reports, foreign post-marketing reports, etc.) they do not provide the kind of information necessary to estimate the incidence of adverse events. Thus, overall incidence figures for adverse reactions associated with the use of selegiline cannot be provided. Many of the adverse reactions seen have been also reported as symptoms of dopamine excess.

Moreover, the importance and severity of various reactions reported often cannot be ascertained. One index of relative importance, however, is whether or not a reaction caused treatment discontinuation. In prospective pre-marketing studies, the following events led, in decreasing order of frequency, to discontinuation of treatment with selegiline: nausea, hallucinations, confusion, depression, loss of balance, insomnia, orthostatic hypotension, increased akinetic involuntary movements, agitation, arrhythmia, bradykinesia, chorea, delusions, hypertension, new or increased angina pectoris and syncope. Events reported only once as a cause of discontinuation are ankle edema, anxiety, burning lips/mouth, constipation, drowsiness/lethargy, dystonia, excess perspiration, increased freezing, gastrointestinal bleeding, hair loss, increased tremor, nervousness, weakness and weight loss.

Experience with ELDEPRYL® (SELEGILINE HYDROCHLORIDE) obtained in parallel, placebo controlled, randomized studies provides only a limited basis for estimates of adverse reaction rates. The following reactions that occurred with greater frequency among the 49 patients assigned to selegiline as compared to the 50 patients assigned to placebo in the only parallel, placebo controlled trial performed in patients with Parkinson's disease are shown in the following Table. None of these adverse reactions led to a discontinuation of treatment.

In all prospectively monitored clinical investigations, enrolling approximately 920 patients, the following adverse events, classified by body system, were reported.

CENTRAL NERVOUS SYSTEM:

Motor/Coordination/Extrapyramidal: increased tremor, chorea, loss of balance, restlessness, blepharospasm, increased bradykinesia, facial grimace, falling down, heavy leg, muscle twitch*, myoclonic jerks*, stiff neck, tardive dyskinesia, dystonic symptoms, dyskinesia, involuntary movements, freezing, festination, increased apraxia, muscle cramps.

Mental Status/Behavioral/Psychiatric: hallucinations, dizziness, confusion, anxiety, depression, drowsiness, behavior/mood change, dreams/nightmares, tiredness, delusions, disorientation, lightheadedness, impaired memory*, increased energy*, transient high*, hollow feeling, lethargy/malaise, apathy, overstimulation, vertigo, personality change, sleep disturbance, restlessness, weakness, transient irritability.

Pain/Altered Sensation: headache, back pain, leg pain, tinnitus, migraine, supraorbital pain, throat burning, generalized ache, chills, numbness of toes/fingers, taste disturbance.

AUTONOMIC NERVOUS SYSTEM: Dry mouth, blurred vision, sexual dysfunction.

CARDIOVASCULAR: Orthostatic hypotension, hypertension, arrhythmia, palpitations, new or increased angina pectoris, hypotension, tachycardia, peripheral edema, sinus bradycardia, syncope.

GASTROINTESTINAL: Nausea/vomiting, constipation, weight loss, anorexia, poor appetite, dysphagia, diarrhea, heartburn, rectal bleeding, bruxism*, gastrointestinal bleeding (exacerbation of preexisting ulcer disease).

GENITOURINARY/GYNECOLOGIC/ENDOCRINE: Slow urination, transient anorgasmia*, nocturia, prostatic hypertrophy, urinary hesitancy, urinary retention, decreased penile sensation*, urinary frequency.

SKIN AND APPENDAGES: Increased sweating, diaphoresis, facial hair, hair loss, hematoma, rash, photosensitivity.

MISCELLANEOUS: Asthma, diplopia, shortness of breath, speech affected.

POSTMARKETING REPORTS: The following experiences were described in spontaneous postmarketing reports. These reports do not provide sufficient information to establish a clear causal relationship with the use of ELDEPRYL® (SELEGILINE HYDROCHLORIDE).

CNS: Seizure in dialyzed chronic renal failure patient on concomitant medications.

*indicates events reported only at doses greater than 10 mg/day.

Incidence of Treatment-Emergent Adverse Experiences in the Placebo-Controlled Clinical Trial

Adverse Event	Number of Patients Reporting Events	
	selegiline hydrochloride N = 49	placebo N = 50
Nausea	10	3
Dizziness/Lightheaded/Fainting	7	1
Abdominal Pain	4	2
Confusion	3	0
Hallucinations	3	1
Dry mouth	3	1
Vivid Dreams	2	0
Dyskinesias	2	5
Headache	2	1
The following events were reported once in either or both groups:		
Ache, generalized	1	0
Anxiety/Tension	1	1
Anemia	0	1
Diarrhea	1	0
Hair Loss	0	1
Insomnia	1	1
Lethargy	1	0
Leg pain	1	0
Low back pain	1	0
Malaise	0	1
Palpitations	1	0
Urinary Retention	1	0
Weight Loss	1	0

OVERDOSAGE:

Selegiline: No specific information is available about clinically significant overdoses with ELDEPRYL® (SELEGILINE HYDROCHLORIDE). However, experience gained during selegiline's development reveals that some individuals exposed to doses of 600 mg d,l selegiline suffered severe hypotension and psychomotor agitation.

Since the selective inhibition of MAO B by selegiline hydrochloride is achieved only at doses in the range recommended for the treatment of Parkinson's disease (e.g., 10 mg/day), overdoses are likely to cause significant inhibition of both MAO A and MAO B. Consequently, the signs and symptoms of overdose may resemble those observed with marketed non-selective MAO inhibitors (e.g., tranylcypromine (PARNATE), isocarboxazide (MARPLAN), and phenelzine (NARDIL)).

Overdose with Non-Selective MAO Inhibition: NOTE: This section is provided for reference; it does not describe events that have actually been observed with selegiline in overdose.

Characteristically, signs and symptoms of non-selective MAOI overdose may not appear immediately. Delays of up to 12 hours between ingestion of drug and the appearance of signs may occur. Importantly, the peak intensity of the syndrome may not be reached for upwards of a day following the overdose. Death has been reported following overdosage. Therefore, immediate hospitalization, with continuous patient observation and monitoring for a period of at least two days following the ingestion of such drugs in overdose is strongly recommended.

The clinical picture of MAOI overdose varies considerably; its severity may be a function of the amount of drug consumed. The central nervous and cardiovascular systems are prominently involved.

Signs and symptoms of overdosage may include, alone or in combination, any of the following: drowsiness, dizziness, faintness, irritability, hyperactivity, agitation, severe headache, hallucinations, trismus, opisthotonus, convulsions, and coma; rapid and irregular pulse, hypertension, hypotension and vascular collapse; precordial pain, respiratory depression and failure, hyperpyrexia, diaphoresis, and cool, clammy skin.

Treatment Suggestions for Overdose

NOTE: Because there is no recorded experience with selegiline overdose, the following suggestions are offered based upon the assumption that selegiline overdose may be modeled by non-selective MAOI poisoning. In any case, up-to-date information about the treatment of overdose can often be obtained from a certified Regional Poison Control Center. Telephone numbers of certified Poison Control Centers are listed in the Physician's Desk Reference (PDR).

Treatment of overdose with non-selective MAOIs is symptomatic and supportive. Induction of emesis or gastric lavage with instillation of charcoal slurry may be helpful in early poisoning, provided the airway has been protected against aspiration. Signs and symptoms of central nervous system stimulation, including convulsions, should be treated with diazepam, given slowly intravenously. Phenothiazine derivatives and central nervous system stimulants should be avoided. Hypotension and vascular collapse should be treated with intravenous fluids and, if necessary, blood pressure titration with an intravenous infusion of a dilute pressor agent. It should be noted that adrenergic agents may produce a markedly increased pressor response.

Respiration should be supported by appropriate measures, including management of the airway, use of supplemental oxygen, and mechanical ventilatory assistance, as required.

Body temperature should be monitored closely. Intensive management of hyperpyrexia may be required. Maintenance of fluid and electrolyte balance is essential.

DOSAGE AND ADMINISTRATION:

ELDEPRYL® (SELEGILINE HYDROCHLORIDE) is intended for administration to Parkinsonian patients receiving levodopa/carbidopa therapy who demonstrate a deteriorating response to this treatment. The recommended regimen for the administration of ELDEPRYL® (SELEGILINE HYDROCHLORIDE) is 10 mg per day administered as divided doses of 5 mg each taken at breakfast and lunch. There is no evidence that additional benefit will be obtained from the administration of higher doses. Moreover, higher doses should ordinarily be avoided because of the increased risk of side effects.

After two to three days of selegiline treatment, an attempt may be made to reduce the dose of levodopa/carbidopa. A reduction of 10 to 30% was achieved with the typical participant in the domestic placebo controlled trials who was assigned to selegiline treatment. Further reductions of levodopa/carbidopa may be possible during continued selegiline therapy.

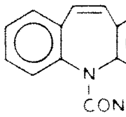
Before prescribing Tegretol, the physician should be thoroughly familiar with the details of this prescribing information, particularly regarding use with other drugs, especially those which accentuate toxicity potential.

DESCRIPTION

Tegretol, carbamazepine USP is an anticonvulsant and specific analgesic for trigeminal neuralgia, available as chewable tablets of 100 mg and tablets of 200 mg for oral administration Its chemical name is 5H-dibenz[b,f]azepine-5-carboxamide, and its structural formula is



Carbamazepine USP is a white to off-white powder, practically insoluble in water and soluble in alcohol and in acetone. Its molecular weight is 236.27

Inactive Ingredients Colloidal silicon dioxide, FD&C Red No 3 (chewable tablets only), FD&C Red No 40 (200-mg tablets only), flavoring (chewable tablets only), gelatin, glycerin, magnesium stearate, sodium starch glycolate (chewable tablets only) starch stearic acid, and sucrose (chewable tablets only)

CLINICAL PHARMACOLOGY

In controlled clinical trials, Tegretol has been shown to be effective in the treatment of psychomotor and grand mal seizures, as well as trigeminal neuralgia

It has demonstrated anticonvulsant properties in rats and mice with electrically and chemically induced seizures It appears to act by reducing polysynaptic responses and blocking the post-tetanic potentiation Tegretol greatly reduces or abolishes pain induced by stimulation of the infraorbital nerve in cats and rats It depresses thalamic potential and bulbar and polysynaptic reflexes, including the linguomandibular reflex in cats. Tegretol is chemically unrelated to other anticonvulsants or other drugs used to control the pain of trigeminal neuralgia The mechanism of action remains unknown

Tegretol tablets are adequately absorbed after oral administration at a slower rate than a solution, thus avoiding undesirably high peak concentrations Tegretol chewable tablets may produce higher peak levels than the same dose given as regular tablets Tegretol in blood is 76% bound to plasma proteins Plasma levels of Tegretol are variable and may range from 0.5-25 μg/ml, with no apparent relationship to the daily intake of the drug Usual adult therapeutic levels are between 4 and 12 μg/ml Following oral administration, serum levels peak at 4 to 5 hours The CSF/serum ratio is 0.22, similar to the 22% unbound Tegretol in serum Because Tegretol may induce its own metabolism, the half-life is also variable. Initial half-life values range from 25-65 hours, with 12-17 hours on repeated doses Tegretol is metabolized in the liver After oral administration of 14C-carbamazepine, 72% of the administered radioactivity was found in the urine and 28% in the feces This urinary radioactivity was composed largely of hydroxylated and conjugated metabolites, with only 3% of unchanged Tegretol Transplacental passage of Tegretol is rapid (30 to 60 minutes), and the drug is accumulated in fetal tissues, with higher levels found in liver and kidney than in brain and lungs

INDICATIONS AND USAGE

Epilepsy: Tegretol is indicated for use as an anticonvulsant drug Evidence supporting efficacy of Tegretol as an anticonvulsant was derived from active drug-controlled studies that enrolled patients with the following seizure types

1 Partial seizures with complex symptomatology (psychomotor, temporal lobe) Patients with these seizures appear to show greater improvement than those with other types

2 Generalized tonic-clonic seizures (grand mal)

3 Mixed seizure patterns which include the above, or other partial or generalized seizures

Absence seizures (petit mal) do not appear to be controlled by Tegretol (see PRECAUTIONS, General)

Trigeminal Neuralgia: Tegretol is indicated in the treatment of the pain associated with true trigeminal neuralgia

Beneficial results have also been reported in glossopharyngeal neuralgia

This drug is not a simple analgesic and should not be used for the relief of trivial aches or pains

CONTRAINDICATIONS

Tegretol should not be used in patients with a history of previous bone marrow depression, hypersensitivity to the drug, or known sensitivity to any of the tricyclic compounds, such as amitriptyline, desipramine, imipramine, protriptyline, nortriptyline etc Likewise, on theoretical grounds its use with monoamine oxidase inhibitors is not recommended Before administration of Tegretol, MAO inhibitors should be discontinued for a minimum of fourteen days, or longer if the clinical situation permits

WARNINGS

Patients with a history of adverse hematologic reaction to any drug may be particularly at risk

Severe dermatologic reactions including toxic epidermal necrolysis (Lyell's syndrome) and Stevens-Johnson syndrome, have been reported with Tegretol These reactions have been extremely rare However, a few fatalities have been reported

Tegretol has shown mild anticholinergic activity, therefore, patients with increased intraocular pressure should be closely observed during therapy

Because of the relationship of the drug to other tricyclic compounds, the possibility of activation of a latent psychosis and, in elderly patients, of confusion or agitation should be borne in mind.

PRECAUTIONS

General: Before initiating therapy, a detailed history and physical examination should be made

Tegretol should be used with caution in patients with a mixed seizure disorder that includes atypical absence seizures, since in these patients Tegretol has been associated with increased frequency of generalized convulsions (see INDICATIONS AND USAGE)

Therapy should be prescribed only after critical benefit-to-risk appraisal in patients with a history of cardiac, hepatic or renal damage, adverse hematologic reaction to other drugs, or interrupted courses of therapy with Tegretol

Information for Patients: Patients should be made aware of the early toxic signs and symptoms of a potential hematologic problem, such as fever, sore throat, ulcers in the mouth, easy bruising, petechial or purpuric hemorrhage, and should be advised to report to the physician immediately if any such signs or symptoms appear.

Since dizziness and drowsiness may occur, patients should be cautioned about the hazards of operating machinery or automobiles or engaging in other potentially dangerous tasks

Laboratory Tests: Complete pretreatment blood counts, including platelets and possibly reticulocytes and serum iron, should be obtained as a baseline If a patient in the course of treatment exhibits low or decreased white blood cell or platelet counts, the patient should be monitored closely Discontinuation of the drug should be considered if any evidence of significant bone marrow depression develops

Baseline and periodic evaluations of liver function, particularly in patients with a history of liver disease, must be performed during treatment with this drug since liver damage may occur The drug should be discontinued immediately in cases of aggravated liver dysfunction or active liver disease

Baseline and periodic eye examinations, including slit-lamp, funduscopy and tonometry, are recommended since many phenothiazines and related drugs have been shown to cause eye changes

Baseline and periodic complete urinalysis and BUN determinations are recommended for patients treated with this agent because of observed renal dysfunction

Monitoring of blood levels (see CLINICAL PHARMACOLOGY) has increased the efficacy and safety of anticonvulsants This monitoring may be particularly useful in cases of dramatic increase in seizure frequency and for verification of compliance In addition measurement of drug serum levels may aid in determining the cause of toxicity when more than one medication is being used

Thyroid function tests have been reported to show decreased values with Tegretol administered alone

Hyponatremia has been reported in association with Tegretol use, either alone or in combination with other drugs

Drug Interactions: The simultaneous administration of phenobarbital, phenytoin, or primidone, or a combination of two, produces a marked lowering of serum levels of Tegretol The effect of valproic acid on Tegretol blood levels is not clearly established, although an increase in the ratio of active 10, 11-epoxide metabolite to parent compound is a consistent finding

The half-lives of phenytoin, warfarin, doxycycline, and theophylline were significantly shortened when administered concurrently with Tegretol Haloperidol and valproic acid serum levels may be reduced when these drugs are administered with Tegretol The doses of these drugs may therefore have to be increased when Tegretol is added to the therapeutic regimen

Concomitant administration of Tegretol with erythromycin, cimetidine, propoxyphene, isoniazid or calcium channel blockers has been reported to result in elevated plasma levels of carbamazepine resulting in toxicity in some cases Also, concomitant administration of carbamazepine and lithium may increase the risk of neurotoxic side effects

Alterations of thyroid function have been reported in combination therapy with other anticonvulsant medications

Breakthrough bleeding has been reported among patients receiving concomitant oral contraceptives and their reliability may be adversely affected

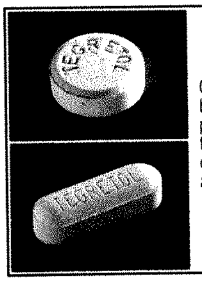
Carcinogenesis, Mutagenesis, Impairment of Fertility: Carbamazepine, when administered to Sprague-Dawley rats for two years in the diet at doses of 25, 75, and 250 mg/kg/day, resulted in a dose-related increase in the incidence of hepatocellular tumors in females and of benign interstitial cell adenomas in the testes of males

Carbamazepine must, therefore, be considered to be carcinogenic in Sprague-Dawley rats Bacterial and mammalian mutagenicity studies using carbamazepine produced negative results The significance of these findings relative to the use of carbamazepine in humans is, at present, unknown

Pregnancy Category C: Tegretol has been shown to have adverse effects in reproduction studies in rats when given orally in dosages 10-25 times the maximum human daily dosage of 1200 mg In rat teratology studies, 2 of 135 offspring showed kinked ribs at 250 mg/kg and 4 of 119 offspring at 650 mg/kg showed other anomalies (cleft palate, 1, talipes 1, anophthalmos, 2) In reproduction studies in rats, nursing offspring demonstrated a lack of weight gain and an unkempt appearance at a maternal dosage level of 200 mg/kg

There are no adequate and well-controlled studies in pregnant women Epidemiological data suggest that there may be an association between the use of carbamazepine during pregnancy and congenital malformations, including spina bifida Tegretol should be used during pregnancy only if the potential benefit justifies the potential risk to the fetus

Retrospective case reviews suggest that, compared with monotherapy, there may be a higher prevalence of teratogenic effects associated with the use of anticonvulsants in combination therapy Therefore, monotherapy is recommended for pregnant women



Only TEGRETOL,
brand of carbamazepine,
provides the prescribing
flexibility of a 100-mg scored
chewable tablet, as well as
a 200-mg scored tablet.

It is important to note that anticonvulsant drugs should not be discontinued in patients in whom the drug is administered to prevent major seizures because of the strong possibility of precipitating status epilepticus with attendant hypoxia and threat to life In individual cases where the severity and frequency of the seizure disorder are such that removal of medication does not pose a serious threat to the patient, discontinuation of the drug may be considered prior to and during pregnancy, although it cannot be said with any confidence that even minor seizures do not pose some hazard to the developing embryo or fetus

Labor and Delivery: The effect of Tegretol on human labor and delivery is unknown

Nursing Mothers: During lactation, concentration of Tegretol in milk is approximately 60% of the maternal plasma concentration

Because of the potential for serious adverse reactions in nursing infants from carbamazepine, a decision should be made whether to discontinue nursing or to discontinue the drug, taking into account the importance of the drug to the mother

Pediatric Use: Safety and effectiveness in children below the age of 6 years have not been established.

ADVERSE REACTIONS

If adverse reactions are of such severity that the drug must be discontinued, the physician must be aware that abrupt discontinuation of any anticonvulsant drug in a responsive epileptic patient may lead to seizures or even status epilepticus with its life-threatening hazards

The most severe adverse reactions have been observed in the hemopoietic system (see boxed WARNING), the skin and the cardiovascular system

The most frequently observed adverse reactions, particularly during the initial phases of therapy, are dizziness, drowsiness, unsteadiness, nausea, and vomiting To minimize the possibility of such reactions, therapy should be initiated at the low dosage recommended

The following additional adverse reactions have been reported

Hemopoietic System Aplastic anemia, agranulocytosis, pancytopenia, bone marrow depression, thrombocytopenia, leukopenia, leukocytosis, eosinophilia, acute intermittent porphyria

Skin Pruritic and erythematous rashes, urticaria, toxic epidermal necrolysis (Lyell's syndrome) (see WARNINGS), Stevens-Johnson syndrome (see WARNINGS), photosensitivity reactions, alterations in skin pigmentation, exfoliative dermatitis, erythema multiforme and nodosum, purpura, aggravation of disseminated lupus erythematosus, alopecia, and diaphoresis In certain cases, discontinuation of therapy may be necessary

Cardiovascular System Congestive heart failure, edema aggravation of hypertension, hypotension, syncope and collapse, aggravation of coronary artery disease, arrhythmias and AV block, primary thrombophlebitis, recurrence of thrombophlebitis, and adenopathy or lymphadenopathy

Some of these cardiovascular complications have resulted in fatalities Myocardial infarction has been associated with other tricyclic compounds

Liver Abnormalities in liver function tests, cholestatic and hepatocellular jaundice, hepatitis

Respiratory System Pulmonary hypersensitivity characterized by fever dyspnea, pneumonitis or pneumonia

Genitourinary System Urinary frequency, acute urinary retention, oliguria with elevated blood pressure, azotemia, renal failure, and impotence Albuminuria, glycosuria, elevated BUN and microscopic deposits in the urine have also been reported

Testicular atrophy occurred in rats receiving Tegretol orally from 4 to 52 weeks at dosage levels of 50 to 400 mg/kg/day Additionally, rats receiving Tegretol in the diet for two years at dosage levels of 25, 75, and 250 mg/kg/day had a dose-related incidence of testicular atrophy and aspermatogenesis In dogs, it produced a brownish discoloration, presumably a metabolite, in the urinary bladder at dosage levels of 50 mg/kg and higher Relevance of these findings to humans is unknown

Nervous System Dizziness, drowsiness, disturbances of coordination, confusion, headache, fatigue, blurred vision, visual hallucinations transient diplopia oculomotor disturbances, nystagmus, speech disturbances, abnormal involuntary movements, peripheral neuritis and paresthesias, depression with agitation, talkativeness, tinnitus, and hyperacusis

There have been reports of associated paralysis and other symptoms of cerebral arterial insufficiency, but the exact relationship of these reactions to the drug has not been established

Digestive System Nausea, vomiting, gastric distress and abdominal pain, diarrhea, constipation, anorexia, and dryness of the mouth and pharynx, including glossitis and stomatitis

Eyes Scattered, punctate, cortical lens opacities, as well as conjunctivitis have been reported Although a direct causal relationship has not been established, many phenothiazines and related drugs have been shown to cause eye changes

Musculoskeletal System Aching joints and muscles, and leg cramps

Metabolism Fever and chills Inappropriate antidiuretic hormone (ADH) secretion syndrome has been reported Cases of frank water intoxication with decreased serum sodium (hyponatremia) and confusion, have been reported in association with Tegretol use (see PRECAUTIONS Laboratory Tests)

Other Isolated cases of a lupus erythematosus-like syndrome have been reported There have been occasional reports of elevated levels of cholesterol HDL cholesterol and triglycerides in patients taking anticonvulsants

A case of aseptic meningitis accompanied by myoclonus and peripheral eosinophilia, has been reported in a patient taking carbamazepine in combination with other medications The patient was successfully dechallenged, and the meningitis reappeared upon rechallenge with carbamazepine

DRUG ABUSE AND DEPENDENCE

No evidence of abuse potential has been associated with Tegretol, nor is there evidence of psychological or physical dependence in humans

OVERDOSAGE

Acute Toxicity

Lowest known lethal dose adults >60 g (39-year-old man) Highest known doses survived adults, 30 g (31-year-old woman), children, 10 g (6-year-old boy), small children 5 g (3-year-old girl)

Oral LD_{50} in animals (mg/kg) mice, 1100-3750, rats, 3850-4025 rabbits, 1500-2680, guinea pigs 920

Signs and Symptoms

The first signs and symptoms appear after 1-3 hours Neuromuscular disturbances are the most prominent Cardiovascular disorders are generally milder, and severe cardiac complications occur only when very high doses (>60 g) have been ingested

Respiration Irregular breathing, respiratory depression

Cardiovascular System Tachycardia hypotension or hypertension, shock conduction disorders

Nervous System and Muscles Impairment of consciousness ranging in severity to deep coma Convulsions, especially in small children Motor restlessness, muscular twitching, tremor, athetoid movements opisthotonos, ataxia, drowsiness dizziness mydriasis, nystagmus, adiadochokinesia ballism psychomotor disturbances, dysmetria Initial hyperreflexia, followed by hyporeflexia

Gastrointestinal Tract Nausea, vomiting

Kidneys and Bladder Anuria or oliguria, urinary retention

Laboratory Findings Isolated instances of overdosage have included leukocytosis, reduced leukocyte count, glycosuria and acetonuria EEG may show dysrhythmias

Combined Poisoning When alcohol, tricyclic antidepressants barbiturates or hydantoins are taken at the same time, the signs and symptoms of acute poisoning with Tegretol may be aggravated or modified

Treatment

The prognosis in cases of severe poisoning is critically dependent upon prompt elimination of the drug, which may be achieved by inducing vomiting, irrigating the stomach, and by taking appropriate steps to diminish absorption If these measures cannot be implemented without risk on the spot, the patient should be transferred at once to a hospital, while ensuring that vital functions are safeguarded There is no specific antidote

Elimination of the Drug. Induction of vomiting

Gastric lavage Even when more than 4 hours have elapsed following ingestion of the drug, the stomach should be repeatedly irrigated, especially if the patient has also consumed alcohol

Measures to Reduce Absorption Activated charcoal, laxatives

Measures to Accelerate Elimination Forced diuresis

Dialysis is indicated only in severe poisoning associated with renal failure Replacement transfusion is indicated in severe poisoning in small children

Respiratory Depression Keep the airways free, resort, if necessary, to endotracheal intubation, artificial respiration and administration of oxygen

Hypotension, Shock Keep the patient's legs raised and administer a plasma expander If blood pressure fails to rise despite measures taken to increase plasma volume, use of vasoactive substances should be considered

Convulsions Diazepam or barbiturates

Warning Diazepam or barbiturates may aggravate respiratory depression (especially in children), hypotension, and coma However barbiturates should not be used if drugs that inhibit monoamine oxidase have also been taken by the patient either in overdosage or in recent therapy (within one week)

Surveillance Respiration, cardiac function (ECG monitoring), blood pressure, body temperature, pupillary reflexes, and kidney and bladder function should be monitored for several days

Treatment of Blood Count Abnormalities If evidence of significant bone marrow depression develops, the following recommendations are suggested (1) stop the drug, (2) perform daily CBC, platelet and reticulocyte counts, (3) do a bone marrow aspiration and trephine biopsy immediately and repeat with sufficient frequency to monitor recovery

Special periodic studies might be helpful as follows (1) white cell and platelet antibodies, (2) 59Fe—ferrokinetic studies, (3) peripheral blood cell typing, (4) cytogenetic studies on marrow and peripheral blood (5) bone marrow culture studies for colony-forming units, (6) hemoglobin electrophoresis for A_2 and F hemoglobin, and (7) serum folic acid and B_{12} levels

A fully developed aplastic anemia will require appropriate, intensive monitoring and therapy, for which specialized consultation should be sought

DOSAGE AND ADMINISTRATION

Monitoring of blood levels has increased the efficacy and safety of anticonvulsants (see PRECAUTIONS, Laboratory Tests) Dosage should be adjusted to the needs of the individual patient A low initial daily dosage with a gradual increase is advised As soon as adequate control is achieved, the dosage may be reduced very gradually to the minimum effective level Tablets should be taken with meals

Epilepsy (see INDICATIONS AND USAGE)

Adults and children over 12 years of age—Initial: 200 mg b i d Increase at weekly intervals by adding up to 200 mg per day using a t i d or q i d regimen until the best response is obtained Dosage should generally not exceed 1000 mg daily in children 12 to 15 years of age and 1200 mg daily in patients above 15 years of age Doses up to 1600 mg daily have been used in adults in rare instances ***Maintenance:*** Adjust dosage to the minimum effective level, usually 800-1200 mg daily

Children 6-12 years of age—Initial: 100 mg b i d Increase at weekly intervals by adding 100 mg per day using a t i d or q i d regimen until the best response is obtained Dosage should generally not exceed 1000 mg ***Maintenance:*** Adjust dosage to the minimum effective level, usually 400-800 mg daily

Combination Therapy: Tegretol may be used alone or with other anticonvulsants When added to existing anticonvulsant therapy, the drug should be added gradually while the other anticonvulsants are maintained or gradually decreased, except phenytoin, which may have to be increased (see PRECAUTIONS, Drug Interactions and Pregnancy Category C)

Trigeminal Neuralgia (see INDICATIONS AND USAGE)

Initial: 100 mg b i d on the first day for a total daily dose of 200 mg This daily dose may be increased by up to 200 mg a day using increments of 100 mg every 12 hours only as needed to achieve freedom from pain Do not exceed 1200 mg daily

Maintenance: Control of pain can be maintained in most patients with 400 mg to 800 mg daily However, some patients may be maintained on as little as 200 mg daily while others may require as much as 1200 mg daily At least once every 3 months throughout the treatment period, attempts should be made to reduce the dose to the minimum effective level or even to discontinue the drug

HOW SUPPLIED

Chewable Tablets 100 mg—round, red-speckled, pink, single-scored (imprinted Tegretol on one side and 52 twice on the scored side)

Bottles of 100	NDC 0028-0052-01
Unit Dose (blister pack)	
Box of 100	
(strips of 10)	NDC 0028-0052-61

Tablets 200 mg—capsule-shaped pink, single-scored (imprinted Tegretol on one side and 27 twice on the scored side)

Bottles of 100	NDC 0028-0027-01
Bottles of 1000	NDC 0028-0027-10
Gy-Pak®—One Unit	
12 bottles—100 tablets each	NDC 0028-0027-65
Unit Dose (blister pack)	
Box of 100	
(strips of 10)	NDC 0028-0027-61

Samples, when available, are identified by the word *SAMPLE* appearing on each tablet

Protect from moisture

Dispense in tight container (USP)

Also available as Tegretol suspension 100 mg/5 ml, in 450 ml bottles

Printed in U S A   C90-34 (Rev 6/90)

A Trial of Thiamine in Alzheimer's Disease

K. A. Nolan, PhD; R. S. Black, MD; K. F. R. Sheu, PhD; J. Langberg; J. P. Blass, MD, PhD

• Because a previous short-term study demonstrated a statistically significant, but not clinically important, improvement in cognitive test scores during thiamine treatment in patients with dementia of the Alzheimer's type, a 12-month, double-blind, parallel-group study was conducted to examine whether long-term administration of thiamine at 3 g/d might slow the progression of dementia of the Alzheimer's type. Fifteen subjects were enrolled and 10 completed the 1-year study. Data are available for two additional subjects through the first 9 months of study. No significant differences were found between the placebo and thiamine groups at any point during the study. In both groups, overall means for the Mini-Mental State Examination, verbal learning, and naming scores decreased significantly over the 12-month study period. These results do not support the hypothesis that long-term administration of thiamine at 3 g/d might slow the progression of dementia of the Alzheimer's type.

(*Arch Neurol.* 1991;48:81-83)

Biochemical abnormalities in thiamine-dependent enzymes in brains and other tissues in patients with dementia of the Alzheimer's type (DAT) have been described elsewhere.[1,2] The activities of thiamine-dependent enzymes in the brains of patients with DAT appear to be decreased to a greater extent than the "nonspecific" reductions in a number of constituents that Bowen et al[3] related to brain atrophy. The reductions are comparable to the "specific" deficits in the cholinergic marker enzyme, choline acetyltransferase.[3] The fact that the decreases in the activities of thiamine-dependent enzymes also occurred in areas of the brain that were histologically relatively unaffected suggests that they are not nonspecific results of tissue damage. Subtle abnormalities in one of these enzymes, transketolase, were also identified in red blood cells and in cultured skin fibroblasts from patients with Alzheimer's disease.[1,2]

A previously published study by Blass et al[4] was designed to test the potential relationship of these observations to the disease process. The results of that study, in which thiamine (vitamin B_1) was administered to patients with DAT at a dose of 3 g/d for 3 months, demonstrated a statistically significant improvement on cognitive testing during the treatment period relative to a comparable placebo period. In this double-blind, placebo-controlled crossover study, each patient received either placebo or thiamine at a dose of 3g/d for 3 months, followed by 3 months of the alternate treatment. Efficacy measures were the Mini-Mental State Examination (MMSE),[5] the dementia rating scale of Blessed et al,[6] and the caregiver-scored Haycox behavioral scale.[7] Mean MMSE scores during treatment with thiamine were significantly higher than MMSE scores during the placebo period, although there was no significant difference observed in scores on either of the behavioral rating scales. Moreover, the thiamine-placebo difference in MMSE scores was small (mean difference, 0.72 ± 0.14).

Although the short-term effect of thiamine was not clinically important, if this small increment in MMSE score could be maintained over longer periods, the overall effect might be to slow the rate of deterioration of cognitive functioning in DAT. A double-blind, placebo-controlled, parallel-group study was undertaken to test this hypothesis. Because no effect of thiamine on behavioral ratings was shown in the first study,[4] efficacy measures were limited to tests of cognitive function.

PATIENTS AND METHODS

Patients

Patients were recruited from the Geriatric Evaluation Service of the Burke Rehabilitation Center, White Plains, NY, a subspecialty clinic that has been described in detail.[8] Each patient recruited for the study had the clinical diagnosis of either probable or possible Alzheimer's disease, by the National Institute of Neurological and Communicative Disorders and Stroke-Alzheimer's Disease and Related Diseases Association criteria[9]; of the 15 patients enrolled in the study, 13 carried a diagnosis of probable Alzheimer's disease and two a diagnosis of possible Alzheimer's disease. Five patients were male, and 10 were female. The patients ranged in age from 59 to 87 years, with a mean age of 76.3 years. At entry, their scores on the MMSE[5] ranged from 8 to 23, with a mean of 16.4. None of the subjects in this study had participated in the previous study of thiamine in DAT. Prior to enrollment, written informed consent was obtained from the patient and from the responsible caregiver.

Ten subjects completed the 1-year study. Two subjects were withdrawn from the study after 3 months or less for lack of compliance. Two other subjects were unavailable for examination at 12 months because of unrelated health problems (their own or a caregiver's). Dropouts and subjects without observations at study completion were evenly distributed across treatment groups. The data from one additional subject had to be eliminated from analyses because of a clerical error that resulted in the patient being given both placebo and thiamine at different times. Characteristics of the 12 patients who completed at least the first 9 months of study and whose data were included in the final analyses are given in Table 1.

Medications

Thiamine hydrochloride and lactose were obtained from a drug manufacturer (Commons Brothers Inc, Elmsford, NY) and were formulated as capsules by staff pharmacists at the Burke Rehabilitation Center. Capsules contained either 1 g of thiamine, made up with lactose excipient, or a lactose

Error	144.40	32	4.51	...	...

*Mini-Mental State Examination scores are given in Table 2.

placebo. Placebo capsules were indistinguishable from thiamine capsules in appearance, size, and weight.

Random assignment of patients to treatment groups was carried out by the pharmacy, where the only records of these assignments were maintained until the study was completed. Caregivers were instructed to have the patient take three capsules a day; patients assigned to the active medication group were receiving 3 g of thiamine a day.

At each clinic visit, subjects were given a 3-month supply of capsules. Study compliance was monitored by pill counts. All 12 subjects who continued taking thiamine beyond the first 3 months of the study had better than 80% compliance.

Procedures

Patients were seen at 3-month intervals. At each clinic visit, the physician performed a brief physical examination. The CERAD (consortium to *e*stablish a *r*egistry for *A*lzheimer's *d*isease) neuropsychological battery[10] was administered to each patient by the same examiner at each visit, including the baseline visit. This battery includes a verbal fluency (categories) measure, a short (15-item) version of the Boston Naming Test, the MMSE, and a constructional praxis test. In addition, there is a 10-item word list learning test and tests of delayed recall and recognition based on the same 10-word list. To avoid potential practice effects in the word list tests, four alternate 10-word lists were used, and an appropriate set of distractors was chosen for each list for the recognition test. The order of presentation of the lists was counterbalanced across subjects, with the constraint that the CERAD list be used for baseline and 12-month evaluations, as required by the CERAD protocol. The MMSE was defined a priori as the primary efficacy measure.

RESULTS

Data from the 10 subjects who completed the full 12 months of study are reported first. As shown in Table 2, subjects assigned to the thiamine and placebo groups were roughly equivalent in terms of MMSE scores at baseline (means of 16.6 and 16.0, respectively). A 2-way (group × time) repeated analysis of variance measures applied to MMSE scores obtained at the five clinic visits (at baseline and at months 3, 6, 9, and 12) (Table 3) indicated no significant difference between the treatment groups ($F_{1,8} = .334$). There is a significant effect of time ($F_{4,32} = 7.866$, $P < .001$), with mean MMSE scores decreasing from 16.3 to 12.5 over the 12-month study period. The Newman-Keuls procedure for tests on the difference between all possible pairs of means was applied to the overall MMSE means. The mean MMSE scores at months 6, 9, and 12 were significantly ($P < .05$) lower than those at baseline. The mean MMSE scores at month 12 were significantly lower than those at all other observations, and mean scores at month 9 were lower than those at all earlier observations. The mean MMSE scores at month 6 were lower than those at baseline. No other differences were significant at the .05 level for the Newman-Keuls tests. The group × time interaction was not significant ($F_{4,32} = 1.603$, $P = .221$).

Scores on the secondary efficacy measures (verbal fluency, naming, constructional praxis, verbal learning, and delayed recognition) were also subjected to two-way (group × time) repeated analyses of variance measures. Delayed recognition performance was expressed as a', a function of hit rate and false-alarm rate. There was no significant difference between the thiamine and placebo groups, and no significant group × time interaction on any of these measures. In the analysis of verbal learning scores, the effect of time was significant ($F_{4,32} = 4.03$, $P = .018$), with the means at month 12 significantly ($P < .05$) lower than those at baseline and month 3 by Newman-Keuls. The effect of time was also significant in naming ($F_{4,32} = 3.047$, $P = .047$), with scores at month 12 significantly ($P < .05$) lower than those at all earlier observations. Mean naming scores at month 6 were also significantly lower than those at month 3 and at baseline. Delayed recall scores were not formally analyzed, due to floor effects; only three of the 10 subjects were ever able to recall more than one item from the 10-word lists, and the most frequent delayed recall score was 0.

Two-way (group × time) repeated analyses of variance measures were also applied to the data for all 12 subjects (six in each group) who completed the first 9 months of the study. As above, the effect of time on MMSE scores was significant ($F_{3,30} = 9.38$, $P < .001$), with the mean MMSE scores at month 9 significantly lower ($P < .05$ by Newman-Keuls) than those at all earlier observations. The effect of time on verbal learning scores was also significant ($F_{3,30} = 5.88$, $P = .003$) and, again, the mean scores at month 9 were significantly lower than those at all earlier observations. There were neither significant treatment group effects nor any significant group × time interactions.

COMMENT

The results of this double-blind, placebo-controlled, parallel-group study do not support the hypothesis that thiamine either improves cognition or slows the progression of cognitive deterioration in patients with DAT. The average MMSE decrement of 3.8 points over a 1-year period observed in these patients is consistent with other published data.[11] However, it must be noted that the rate of change in MMSE scores varied greatly among patients, with two patients, both of whom were in the placebo group, showing no decrement in MMSE scores from baseline to month 12, while other patients lost as many as 12 MMSE points over the same period.

Although these negative results are based on relatively small samples (10 subjects over 12 months, and 12 subjects over 9 months), the positive results obtained by Blass et al[4] were based on an equally small sample (11 subjects). In addition, the absence of a significant effect of thiamine in this study is not a matter of there being a small, but statistically insignificant, difference between the two groups in the predicted direction. On the contrary, the tendency was for more rapid deterioration in the thiamine-treated group than in the placebo group.

The inclusion of other secondary efficacy measures was intended to increase sensitivity to effects in specific areas of cognition that might not be detected by a single, global measure of cognition, such as the MMSE. If, for example, thiamine were effective in improving constructional praxis, the one-point difference in MMSE score that could result from such improvement would be difficult to detect. The use of the CERAD neuropsychological battery provided more detailed evaluations of several specific cognitive domains, including verbal fluency, naming, constructional praxis, and verbal learning. The fact that MMSE scores, verbal learning scores, and naming scores were seen to decrease significantly over time confirms that these measures are sufficiently sensitive to changes in ability in these domains. The absence of significant effects of thiamine is, within at least these three tests, not likely to be due to lack of sensitivity in the outcome measures.

Because this study employed a parallel-group design, as opposed to the cross-over design used in the previous study, it constitutes a more conservative test of the effect of thiamine on cognition in DAT. The previous study examined the effect of short-term administration of thiamine, and the magnitude of the effect in that study was very small (1.3 points on the MMSE). Cross-over studies are less appropriate for the investigation of long-term effects and are subject to carry-over effects and order effects.[12] In a study of long-term effects, such as this one, and especially when maturational factors are expected to come into play, as in progressive dementia, a parallel-group design yields a straightforward interpretation of the results. These results do not support the hypothesis that a 3-g/d dose of thiamine is effective in slowing cognitive deterioration in DAT.

These studies were supported by the National Institutes of Health grant AG 03853, the Will Rogers Institute, White Plains, NY, and the Winifred Masterson Burke Relief Foundation, White Plains, NY.

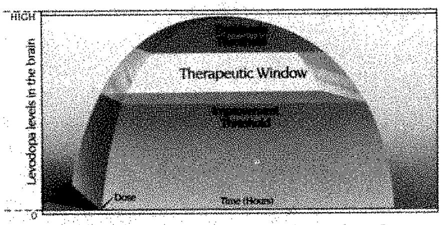
Sinemet®...for many patients with Parkinson's disease, the foundation of therapy for 15 years.
Sinemet®
(Carbidopa-Levodopa)
Power and Precision
Only Sinemet® provides the power to re-establish dopamine levels in the brain and the precision to adjust dosage to meet the individual needs of the patient.



Maintaining Dopamine Levels Within the Therapeutic Window *The aim of clinical intervention in Parkinson's disease is to maintain dopamine levels within a therapeutic window. The three dosage strengths of Sinemet® help meet this challenge by providing both the power to replenish dopamine levels in the brain and the precision to adjust to individual patient needs.*

Managing Parkinson's disease therapy can be complex. The critical need is to maintain dopamine levels in the brain within an ever-narrowing therapeutic window. A window that is different in every patient and one that changes over time because of the progressive nature of the disease.

Dopamine replacement is the mainstay of therapy in Parkinson's disease. And, only Sinemet® has the power to re-establish dopamine levels in the brain.

But, power alone is not enough. Sinemet® also provides you the flexibility to meet the individual needs of the patient...by changing dosage strength or frequency...or by changing the ratio of carbidopa and levodopa.

Nothing else gives you this power and precision to manage the signs and symptoms of Parkinson's disease like Sinemet®.

As with levodopa, SINEMET* may cause involuntary movements and mental disturbances. These reactions are thought to be due to increased brain dopamine levels following administration of levodopa.

Please see a brief summary of prescribing information on the adjoining page.

Sinemet®

For many patients with Parkinson's disease

Dosage Guidelines

Individualized dosage—a key to clinical success with Sinemet®

- Begin when symptoms first interfere with normal function
- Adjust as necessary to help maintain relief of symptoms

1

For initial therapy...Start with:

SINEMET 25-100

containing 25 mg carbidopa (anhydrous equivalent) and 100 mg levodopa

one tablet t.i.d.

If necessary, to control symptoms, dosage may be increased by one tablet every day or every other day until a dosage of eight tablets of Sinemet 25-100 a day is reached.

2

When it is evident that patients need more levodopa...Transfer to:

SINEMET 25-250

containing 25 mg carbidopa (anhydrous equivalent) and 250 mg levodopa

one tablet t.i.d.

If still more levodopa is necessary, dosage with Sinemet 25-250 may be increased by one-half to one tablet every day or every other day to a maximum of eight tablets a day.

3

When individualizing dosage...Titrate with:

SINEMET 10-100

containing 10 mg carbidopa (anhydrous equivalent) and 100 mg levodopa

or SINEMET 25-100

or SINEMET 25-250

The optimum daily dosage of Sinemet must be determined by careful titration in each patient. Tablets of the three strengths may be given separately or combined as needed to provide the optimum daily dosage.

For patients transferred from levodopa

DISCONTINUE LEVODOPA AT LEAST 8 HOURS BEFORE STARTING SINEMET. The starting dose for Sinemet should provide about 25 percent of previous levodopa requirements. (Patients receiving less than 1500 mg of levodopa a day should be started on one tablet of Sinemet 25-100 t.i.d. or q.i.d.)

Sinemet®
(Carbidopa-Levodopa)

When SINEMET is to be given to patients who are being treated with levodopa, levodopa must be discontinued at least 8 hours before therapy with SINEMET is started. In order to reduce adverse reactions, it is necessary to individualize therapy. See the WARNINGS (below) and DOSAGE AND ADMINISTRATION sections in the Prescribing Information before initiating therapy.

Contraindications: MAO inhibitors and SINEMET should not be given concomitantly. MAO inhibitors must be discontinued at least 2 weeks prior to initiating therapy with SINEMET.

SINEMET is contraindicated in patients with known hypersensitivity to this drug and in narrow-angle glaucoma.

Because levodopa may activate a malignant melanoma, it should not be used in patients with suspicious, undiagnosed skin lesions or history of melanoma.

Warnings: Levodopa must be discontinued at least 8 hours before SINEMET is started. SINEMET should be substituted at a dosage that will provide approximately 25 percent of the previous levodopa dosage. (See DOSAGE AND ADMINISTRATION section of Prescribing Information.) Patients taking SINEMET should be instructed not to take additional levodopa unless prescribed.

As with levodopa, SINEMET may cause involuntary movements and mental disturbances. These reactions may be due to increased brain dopamine following administration of levodopa. All patients should be observed carefully for development of depression with concomitant suicidal tendencies. Treat with caution patients with past or current psychoses. *Because carbidopa permits more levodopa to reach the brain and, thus, more dopamine to be formed, dyskinesias may occur at lower dosages and sooner with* SINEMET *than with levodopa.* Occurrence of dyskinesias may require dosage reduction.

SINEMET should be administered cautiously to patients with severe cardiovascular or pulmonary disease, bronchial asthma, renal, hepatic or endocrine disease.

Exercise care in administering SINEMET, as with levodopa, to patients with history of myocardial infarction who have residual atrial, nodal, or ventricular arrhythmias. In such patients, cardiac function should be monitored with particular care during period of initial dosage adjustment, in a facility with provisions for intensive cardiac care.

As with levodopa, there is possibility of upper GI hemorrhage in patients with history of peptic ulcer.

A symptom complex resembling the neuroleptic malignant syndrome including muscular rigidity, elevated body temperature, mental changes, and increased serum creatine phosphokinase has been reported when antiparkinsonian agents were withdrawn abruptly. Therefore, patients should be observed carefully when the dosage of SINEMET is reduced abruptly or discontinued, especially if the patient is receiving neuroleptics.

Usage in Pregnancy and Lactation: Although effects of SINEMET on human pregnancy and lactation are unknown, both levodopa and combinations of carbidopa and levodopa have caused visceral and skeletal malformations in rabbits. Use of SINEMET in women of childbearing potential requires that anticipated benefits of the drug be weighed against possible hazards to mother and child. SINEMET should not be given to nursing mothers.

Usage in Children: Safety of SINEMET in patients under 18 has not been established.

Precautions: As with levodopa, periodic evaluations of hepatic, hematopoietic, cardiovascular, and renal function are recommended during extended therapy.

Patients with chronic wide-angle glaucoma may be treated cautiously with SINEMET provided intraocular pressure is well controlled and patient is monitored carefully for changes in intraocular pressure during therapy.

Laboratory Tests: Abnormalities in laboratory tests may include elevations of liver function tests such as alkaline phosphatase, SGOT (AST), SGPT (ALT), lactic dehydrogenase, and bilirubin. Abnormalities in protein-bound iodine, blood urea nitrogen, and positive Coombs test have also been reported. Commonly, levels of blood urea nitrogen, creatinine, and uric acid are lower during administration of SINEMET than with levodopa.

SINEMET may cause a false-positive reaction for urinary ketone bodies when a test tape is used for determination of ketonuria. This reaction will not be altered by boiling the urine specimen. False-negative tests may result with the us of glucose-oxidase methods of testing for glucosuria.

Drug Interactions: Caution should be exercised when the following dru are administered concomitantly with SINEMET.

Symptomatic postural hypotension can occur whe SINEMET is added to the treatment of a patient receiving ar tihypertensive drugs. Therefore, when therapy with SINEME is started, dosage adjustment of the antihypertensive dr may be required. For patients receiving monoamine oxidas inhibitors, see CONTRAINDICATIONS (above).

There have been rare reports of adverse reactions, i cluding hypertension and dyskinesia, resulting from the co comitant use of tricyclic antidepressants and SINEMET.

Phenothiazines and butyrophenones may reduce th therapeutic effects of levodopa. In addition, the beneficial e fects of levodopa in Parkinson's disease have been reporte to be reversed by phenytoin and papaverine. Patients takin these drugs with SINEMET should be carefully observed f loss of therapeutic response.

Adverse Reactions: Most common serious adverse rea tions occurring with SINEMET are choreiform, dystonic, ar other involuntary movements. Other serious adverse rea tions are mental changes including paranoid ideation ar psychotic episodes, depression with or without developme of suicidal tendencies and dementia. Convulsions also ha occurred; however, a causal relationship with SINEMET h not been established.

A common but less serious effect is nausea.

Less frequent adverse reactions are cardiac irregulariti and/or palpitation, orthostatic hypotensive episode bradykinetic episodes (the "on-off" phenomenon), anore ia, vomiting, and dizziness.

Rarely, GI bleeding, development of duodenal ulc hypertension, phlebitis, hemolytic and non-hemolyt anemia, thrombocytopenia, leukopenia, and agranulocyto have occurred.

Laboratory tests which have been reported to be abn mal are alkaline phosphatase, SGOT (AST), SGPT (ALT), la tic dehydrogenase, bilirubin, blood urea nitrogen, prote bound iodine, and Coombs test.

Other adverse reactions that have been reported w levodopa are: *Nervous System:* ataxia, numbness, increas hand tremor, muscle twitching, muscle cram blepharospasm (which may be taken as an early sign of cess dosage, consideration of dosage reduction may made at this time), trismus, activation of latent Horner's sy drome. *Psychiatric:* confusion, sleepiness, insom nightmares, hallucinations, delusions, agitation, anxie euphoria. *Gastrointestinal:* dry mouth, bitter taste, sialorrh dysphagia, bruxism, hiccups, abdominal pain and distre constipation, diarrhea, flatulence, burning sensation tongue. *Metabolic:* weight gain or loss, edema. *Integumenta* malignant melanoma (see also CONTRAINDICATION flushing, increased sweating, dark sweat, skin rash, loss of h *Genitourinary:* urinary retention, urinary incontinence, d urine, priapism. *Special Senses:* diplopia, blurred vision, dila pupils, oculogyric crises. *Miscellaneous:* weakness, faintne fatigue, headache, hoarseness, malaise, hot flashes, sense stimulation, bizarre breathing patterns, neuroleptic maligna syndrome.

Overdosage: Management of acute overdosage w SINEMET is basically the same as management of acute o dosage with levodopa; however, pyridoxine is not effect in reversing the actions of SINEMET.

How Supplied: Tablets SINEMET 10-100, SINEMET 25-1 and SINEMET 25-250 are supplied in bottles of 100 and u dose packages of 100.

Storage: Tablets SINEMET 10-100 and Tablets SINEM 25-250 must be protected from light.

Nystagmus of Pelizaeus-Merzbacher Disease

A Magnetic Search-Coil Study

Jonathan D. Trobe, MD; James A. Sharpe, MD; David K. Hirsh, MD; Stephen S. Gebarski, MD

• Magnetic search-coil oculography of three brothers with clinically diagnosed Pelizaeus-Merzbacher disease disclosed the presence of binocular elliptical pendular nystagmus in two patients in whom the waveform of the nystagmus was not obvious on inspection. This study, the first reported application of high-resolution oculography to Pelizaeus-Merzbacher disease, also demonstrated primary position upbeat nystagmus in all three patients. The importance of finding this combination of elliptical pendular and upbeat nystagmus is that it is not described in any other childhood neurodegenerative states and, in combination with supportive clinical history and magnetic resonance imaging, may be so characteristic of Pelizaeus-Merzbacher disease that a strong presumptive diagnosis can be made.

(*Arch Neurol.* 1991;48:87-91)

Pelizaeus-Merzbacher disease (PMD) is an inherited disorder of central nervous system myelin, with neonatal-, childhood-, and adult-onset forms.[1] Among the leukodystrophies, PMD is distinctive in that an unusual binocular pendular nystagmus and head tremor typically herald its onset.[1]

Two previous conventional electronystagmographic studies of PMD using electro-oculographic leads showed prolonged slow phases[2] and unusually large amplitudes[3] of caloric-induced nystagmus. The authors of the latter article suggested that these electronystagmographic abnormalities might be pathognomonic of PMD.

We have performed high-resolution oculographic examinations of the three maternal uncles of a 23-month-old male infant (our proband), each of whom was clinically diagnosed as having PMD (Fig 1). Our oculographic study differs from previously published reports in using a magnetic search coil, which permits more precise assessment of low-amplitude eye movements (in all directions) than does conventional electronystagmography. We did not find the previously described abnormalities of caloric-induced nystagmus,[2,3] but we documented an elliptical trajectory in two patients and a primary position upbeat nystagmus in all three patients that were not obvious by inspection.

PATIENTS AND METHODS

All three patients underwent complete neurological and neuro-ophthalmological examination, video-taping of eye movements, and magnetic resonance imaging.

Oculography was conducted on each affected adult patient, using a scleral silicone contact ring with a wire wound within its outer rim. The right eye was recorded. Patients were seated with the head centered in 0.18-cubic-meter magnetic coils consisting of two pairs of coils, one coil on each side, and one above and one below the head (CNC Engineering, Seattle, Wash). Analogue signals of eye position were direct-current coupled, amplified, low-pass filtered at 500 Hz, and recorded on analogue magnetic tape and, simultaneously, on an ink-jet rectilinear polygraph. Head position was similarly monitored with a search-coil monitor

Fig 1.—Family pedigree. Affected patients are designated by solid symbols; the proband is designated by the arrow.

*Including ophthalmoscopy.
†Magnetic search-coil oculography.

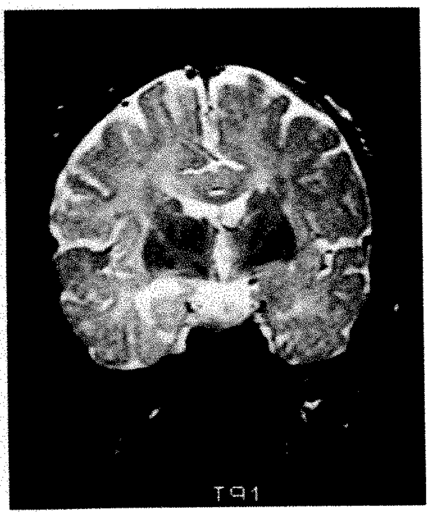

Fig 2.—Patient 1. Coronal brain magnetic resonance imaging. T_2-weighted image shows increased intensity in all visualized white matter, most notable when the gray matter intensity is compared with it. Normally, the gray matter should have higher signal than does the white matter. There is also decreased intensity in the basal ganglia, perhaps related to excessive iron deposition.

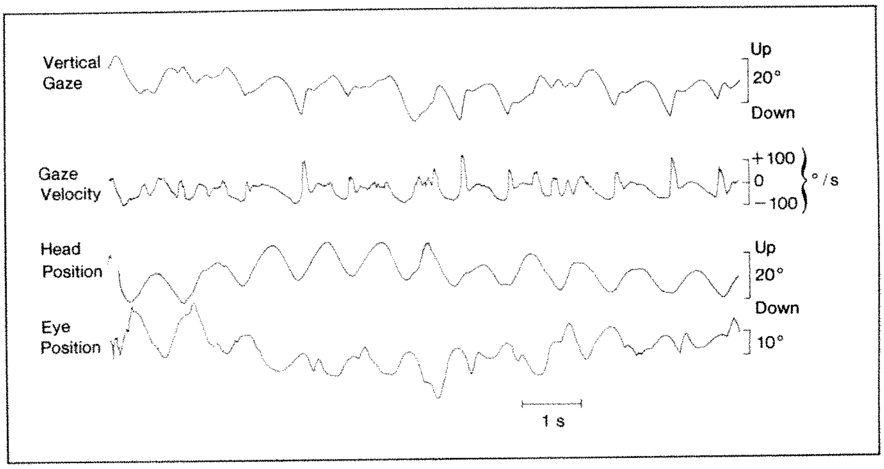

Fig 3.—Patient 1. High-resolution oculography. Vertical vestibulo-ocular reflex (VOR) during active sinusoidal motion of the head in pitch at approximately 1 Hz. The upward VOR has lower gain than does the downward VOR, so that during downward head motion, gaze (the sum of eye position plus head position) is directed downward. If the VORs were normal, vertical gaze (top channel) would be a straight line. The unbalanced VOR is compensated by upward quick phases that are evident as upward spikes of gaze velocity (second channel), causing upbeat nystagmus. Vertical saccades and nystagmus quick phases were abnormally slow.

on a lightweight headband, while the head was restrained by occipital and chin supports.

Patients viewed a rear-projected laser target reflected from mirrors mounted on galvanometer motors, subtending 0.25° of visual angle, and rear projected on a translucent screen. Eye movements were recorded while the patient fixated the target and in darkness. Pursuit movements were recorded while the patient pursued the laser target driven by a computer in sine waves, horizontally or vertically, at peak-to-peak amplitudes of 20° and frequencies of 0.25, 0.5, and 1.0 Hz. Saccades were elicited by step changes in target position at unpredictable intervals, directions, and amplitudes of 5°, 10°, and 20°.

The horizontal vestibulo-ocular reflex (VOR) was tested in darkness, while patients were seated in a vestibular chair rotated sinusoidally at peak-to-peak amplitudes of 20° and frequencies of 0.25, 0.5, and 1.0 Hz. The vertical VOR was assessed during active vertical head movement at the same peak amplitude and frequencies, while head movement was paced with the sound of a metronome. Patients attempted to fixate an imaginary stationary target in darkness.

REPORT OF CASES (Table)

CASE 1.—This 25-year-old man developed abnormal eye movements at 6 weeks of age. He was diagnosed as having had cerebral palsy at the age of 18 months because of delayed milestone acquisition. At the age of 5 years, he had been described as having had esotropia, bilateral nystagmus, and pale optic discs. By the age of 12 years, he was wheelchair bound. On our examination, at the age of 25 years, he was alert and oriented in all spheres, knew the president's name, and could do simple addition and spelling. His speech was scanning. Upper extremity strength was normal, but lower extremity strength was 1/5 with marked spasticity, and all limbs displayed ataxia. Muscle stretch reflexes were hyperactive, with clonus at the ankles, and plantar reflexes were extensor bilaterally. Sensation was normal.

His visual acuity was 20/80 OD, and 20/100 OS. There was temporal optic disc pallor bilaterally. His eyes were aligned in all positions of gaze. Nystagmus was not evident in the primary position, but the patient had horizontal jerk nystagmus in the extremes of lateral gaze and upbeating nystagmus in upgaze. Saccadic velocities were normal, and pursuit movements were saccadic.

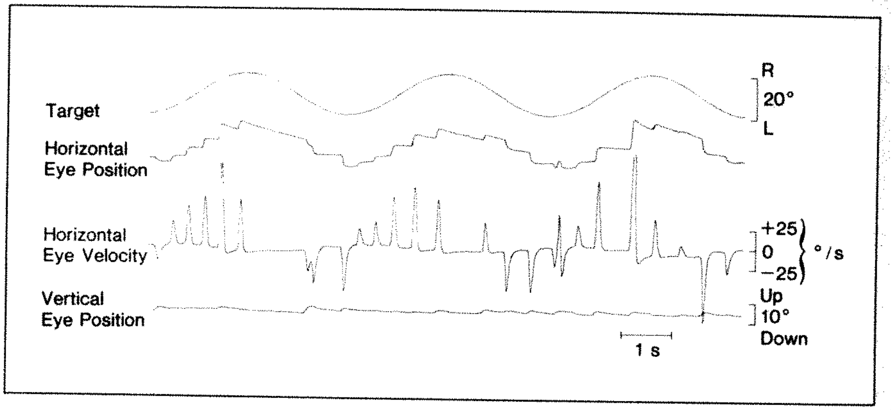

Fig 4.—Patient 1. High-resolution oculography. Horizontal smooth pursuit of a 0.25-Hz target is saccadic to the right. The horizontal eye calibration (channel 2) is the same as the target calibration (channel 1). The fourth channel illustrates low-amplitude upbeat nystagmus in the primary position; upward quick phases are slowed, as are all vertical saccades. R indicates right; and L, left.

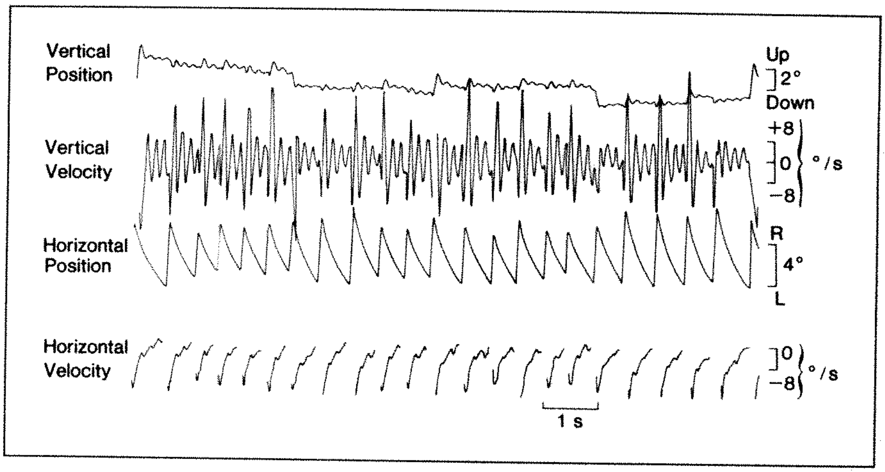

Fig 5.—Patient 2. High-resolution oculography reveals low-amplitude vertical pendular nystagmus superimposed on upbeat nystagmus. The eye is near the vertical midposition. The horizontal position demonstrates right-beating nystagmus, and the horizontal velocity record (bottom trace) shows sinusoidal oscillations superimposed on the leftward slow phases of the horizontal nystagmus. Since the large (0.2° to 0.3°) amplitude vertical pendular oscillations are 90° out of phase, with the miniature horizontal oscillations, the pendular nystagmus is elliptical. The combination of upbeating and right-beating nystagmus also caused diagonal jerk nystagmus. R indicates right; and L, left.

Magnetic resonance imaging (T_2-weighted) demonstrated very severe brain atrophy, increased signal in white matter, and decreased signal in basal ganglia and thalami (Fig 2), a pattern considered typical of PMD.[4-7]

The oculographic examination revealed primary position rightward-beating nystagmus that increased on rightward gaze, and leftward-beating nystagmus on leftward gaze. There was upbeating nystagmus in primary position, upgaze, and downgaze that did not change in the darkness (Fig 3). Horizontal saccades had normal velocity and latency, but they were hypometric to the left and accurate to the right. Upward saccades were mildly slowed, and downward saccades had very reduced peak velocities. Both horizontal (Fig 4) and vertical smooth pursuits were severely reduced in velocity. The upward VOR had very low gain (ratio of smooth eye movement velocity to head velocity), and the downward VOR had mild gain reduction. Warm- (44°C) and cold- (30°C) water caloric responses from each ear were normal.

Case 2.—This 22-year-old man was also diagnosed as having cerebral palsy. His mother noticed his nystagmus before he was 2 months old. At the age of 4 years, he was found to have vertical pendular nystagmus and normal optic discs. He never reached normal cognitive development and became wheelchair bound at 15 years of age. On our examination, at 22 years of age, he was fully oriented. His speech was fluent, although scanning. Both short- and long-term memory were good, yet he was poor at calculations and unable to interpret proverbs. His muscle strength and bulk were normal in the arms, although finger dexterity was poor. Lower extremity strength was 5/5 proximally with increased tone and 1/5 distally with decreased tone and bulk. He had severe truncal and appendicular ataxia. Muscle stretch reflexes were 1+ in the arms and 3+ at the knees, with sustained clonus at the ankles. Plantar responses were flexor. Sensation was intact.

His visual acuity was 20/70 OD and 20/80 OS. Pupillary reactions, color vision, and confrontation visual fields were normal. There was bilateral optic disc pallor. He had a 40-prism-diopter esotropia in primary position. The eyes appeared to be still in the primary position, but ophthalmoscopic examination showed pendular nystagmus. There was horizontal jerk nystagmus on right and left lateral gaze, and upbeat nystagmus on upgaze. Saccadic velocities were grossly normal, and pursuit movements were saccadic.

Magnetic resonance imaging revealed severe cerebral cortical, midbrain, and cerebellar atrophy. The T_2-weighted images demonstrated diffusely increased white matter signal, most notable in the cerebrum. The signal aberrations were similar but less marked than those in patient 1.

The oculographic examination revealed vertical and horizontal pendular nystagmus in the primary position, with the vectors approximately 90° out of phase, causing an elliptical trajectory. The pendular nystagmus persisted in darkness. A low-amplitude (1°) upbeat nystagmus was superimposed on the pendular nystagmus (Fig 5); it increased in amplitude on upgaze. The vertical amplitude of pendular nystagmus was 12 to 20 arc-minutes peak to peak, and the horizontal amplitude was 3 to 4 arc-minutes peak to peak. There was rightward-beating nystagmus in primary position and on rightward gaze, and leftward-beating nystagmus on leftward gaze. Upward saccadic velocities were normal, but downward velocities were slow. Vertical and horizontal pursuit movements had low gain (ratio of smooth eye movement velocity to target velocity). Vertical and horizontal VOR gains were normal. Warm- and cold-water caloric stimulations of each ear showed normal slow phases of nystagmus.

Case 3.—This 20-year-old man was noted to have nystagmus at about 2 months of age. He was slow to acquire developmental milestones and, like his brothers, was diagnosed as having had cerebral palsy. At 3 years of age, he was described as having had a 10-prism-diopter intermittent esotropia, coarse pendular nystagmus in all fields of gaze, and slightly pale optic discs. At 20 years of age, he ambulated with Canadian crutches. His speech was dysarthric. Strength was nearly full in the arms and legs, but only 3/5 in the feet. Muscle tone was normal in the arms and increased in the legs. He had moderate ataxia. Muscle stretch reflexes were 3+ at the elbows and 1+ elsewhere, with clonus at the ankles. Extensor plantar responses were present bilaterally.

The patient's visual acuity was 20/200 OD and 20/200 OS. There was bilateral optic disc pallor. Saccadic velocities were normal, and smooth pursuit was saccadic. He had fine shimmering eye movements in the primary position, with a larger vertical than horizontal component. On right and left lateral gaze, there was large-amplitude low-frequency laterally beating jerk nystagmus.

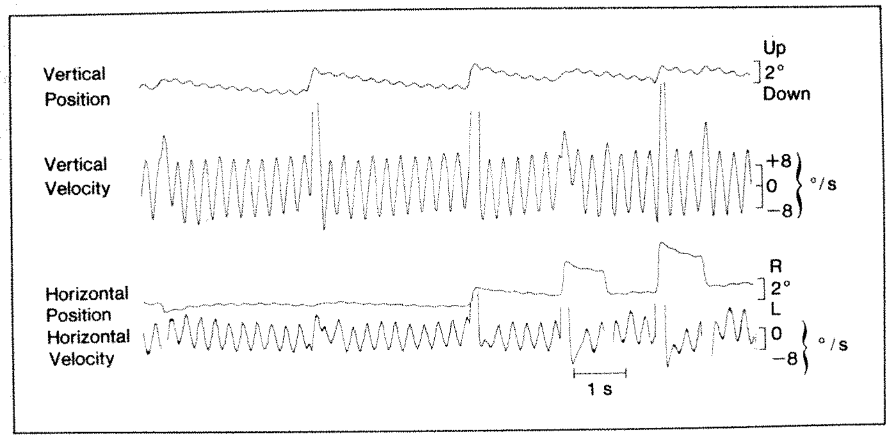

Fig 6.—Patient 3. High-resolution oculography. Pendular nystagmus is evident in the vertical and horizontal positions and velocity records. The amplitude of the vertical oscillations was about twice that of the horizontal oscillations. The vertical and horizontal oscillations are 20° out of phase, so that the elliptical nystagmus resulting from the amplitude and phase disparity between the vertical and horizontal oscillations is almost diagonal. The eyes move up to the left and down to the right. Upbeat nystagmus is evident in the vertical position trace. The vertical pendular nystagmus is superimposed on the slow phases of the upbeat nystagmus. The patient was attempting to fixate a stationary target. Both the elliptical and the upbeat nystagmus persisted unchanged in darkness. R indicates right; and L, left.

Magnetic resonance imaging showed moderate brain atrophy, and T_2-weighted images demonstrated white-matter signal aberrations similar to those of patient 2, but less prominent.

The oculographic examination revealed elliptical pendular nystagmus in the primary position, with the horizontal and vertical vectors approximately 20° out of phase. The vertical pendular oscillations had a peak-to-peak amplitude of 30 to 45 arc-minutes, and the horizontal pendular oscillations had peak-to-peak amplitudes of 8 to 12 arc-minutes (Fig 6), a waveform that was not altered by darkness. Primary position upbeat nystagmus was superimposed on the elliptical nystagmus. Horizontal and upward saccades were of normal velocity; downward saccades were slowed. Vertical and horizontal smooth pursuit velocities were mildly reduced in all directions. The vertical and horizontal VOR gains were normal. Warm-water caloric responses were normal in each ear.

This patient has a fraternal twin brother who refused physical examination. His family described him as physically normal, being able to hold a manual job and drive a car, but learning disabled such that he could not finish high school.

Our proband, aged 23 months, could not be studied oculographically because of his age. To external inspection and on ophthalmoscopy, he displayed an elliptical pendular nystagmus in all positions of gaze. White blood cell arylsulfatase A and galactocerebrosidase activities and plasma levels of very-long-chain fatty acids were normal.

COMMENT

Seitelberger[1] divided the clinical patterns of PMD by age at onset into six types, the most common of which are classical (infantile-onset), connatal (present at birth), and the Lowenberg-Hill (adult-onset) type. The classical and connatal forms of PMD typically have X-linked recessive inheritance, whereas the adult-onset type has autosomal dominant inheritance.[1] However, there are cases of both classical[8] and connatal[9] PMD with apparent autosomal recessive inheritance.

Of the infantile form, Pelizaeus[10] wrote "... the disorder manifested itself during infancy by aimless, wandering eye movements," referring to the nystagmus, which, together with head tremor, make up the first signs of PMD. Often described as "wobbly" or pendular, the nystagmus is followed by progressive spasticity, ataxia, tremor, choreiform or athetotic movements, optic atrophy, and cognitive deterioration. Death usually occurs within the first few years of life in the connatal form of PMD and in the second or third decade of life in the classical form.

Koeppen et al[11] found the absence of a myelin protein, called *proteolipid apoprotein* (proteolipid protein PLP or lipophilin), in two cases of PMD from a family with X-linked recessive inheritance. The authors suggested that the absence of proteolipid protein results in defective assembly of myelin sheaths, thus making PMD a dysmyelinating disease.

Nystagmus is a critical distinguishing feature of PMD, whose differential diagnosis includes metachromatic leukodystrophy, adrenoleukodystrophy, Krabbe disease, Cockayne's syndrome, and neuroaxonal degeneration.[12] To our knowledge, none of these entities is associated with the pendular nystagmus found in PMD, except Cockayne's syndrome,[13] an autosomal recessive leukodystrophy with a pattern of myelin loss histologically similar to PMD. Indeed, Seitelberger[1] considered Cockayne's syndrome to be a special type of PMD. It is distinguished from PMD by multiple dysmorphic features and the presence of basal ganglia calcifications.[13,14]

If other neurologic signs of PMD, besides nystagmus, are not yet prominent, then a sporadic case of PMD may be confused with congenital nystagmus or spasmus nutans. Congenital nystagmus is a binocular pendular or jerk nystagmus, which is almost always horizontal, rarely purely vertical, and may be associated with head tremor.[15,16] Most infants with congenital nystagmus are otherwise neurologically normal.[17] In its complete form, spasmus nutans is a syndrome consisting of a triad of pendular (usually horizontal) nystagmus, head nodding, and torticollis, with onset in the first year of life. It is infrequently associated with central nervous system pathology, and usually resolves spontaneously in 1 to 4 years.[17,18]

Magnetic search-coil oculography in our patients with PMD disclosed, in two of the three patients, a pattern of pendular nystagmus that has not been reported to appear in any other childhood neurodegenerative disorders. Its distinctive waveform, which could not be resolved by inspection, consisted oculographically of a sinusoidal oscillation in both eyes, with horizontal and vertical vectors that were out of phase, and of unequal amplitude, making the eyes' trajectory elliptical. We could not confirm the previously reported conventional electronystagmographic findings of prolonged slow phases and unusually large amplitudes of caloric-induced nystagmus.[2,3]

Pendular nystagmus is acquired in two diseases affecting adults: multiple sclerosis[19] and brain-stem stroke.[20] In some cases, this pendular nystagmus is associated with synchronous oscillations of the palate and other branchial muscles, a combination termed *oculopalatal myoclonus*.[21] In a study of 35 cases of acquired pendular nystagmus in multiple sclerosis, Aschoff et al[19] concluded that it resulted from cerebellar nuclear damage. Gresty et al[22] suggested instead that the responsible lesion is located near the oculomotor nuclei.

A feature common to each of our patients was upbeat nystagmus in primary position. Previous clinical pathological correlations of upbeat nystagmus have identified damage in the pontomedullary tegmentum.[23-26] This may be explained by disruption of the ventral tegmental pathway for the upward VOR, causing imbalance in the vertical VOR.[27] Thus, there is evidence to implicate dysmyelination in the pontomedullary tegmentum as the probable cause of the upbeat nystagmus and, perhaps, the elliptical nystagmus as well. Normality of the horizontal and vertical VORs in our patients implies that involvement of vestibular smooth eye movement pathways is not responsible for the elliptical pendular nystagmus of PMD.

We suggest that the value of recording eye motion in PMD by a high-resolution technique such as search coil lies in verifying the elliptical pendular and upbeat nystagmus that often cannot be resolved by inspection. The presence of this distinctive eye movement abnormality, in conjunction with appropriate magnetic resonance imaging findings, strongly supports a diagnosis of PMD.

This study was supported by Medical Research Council of Canada grants ME5509 and MT5404 (Dr Sharpe).

SANDOZPHARMACEUTICALS
Corporation, E. Hanover, NJ 07936 (201) 503-7500

C-CAF-0689-01
© 1991 Sandoz Pharmaceuticals Corporation

Cafergot®

(ergotamine tartrate and caffeine) tablets, USP
(ergotamine tartrate and caffeine) suppositories, USP

DESCRIPTION

Cafergot® (ergotamine tartrate and caffeine) Tablet

ergotamine tartrate USP	1 mg
caffeine USP	100 mg

Inactive Ingredients: acacia, carnauba wax, lactose, methylparaben, povidone, propylparaben, sodium benzoate, sorbitol, starch, stearic acid, sucrose, synthetic black ferric oxide, synthetic red ferric oxide, synthetic yellow ferric oxide, talc, tartaric acid, and titanium dioxide.

Cafergot® (ergotamine tartrate and caffeine) Suppository

ergotamine tartrate USP	2 mg
caffeine USP	100 mg

Inactive Ingredients: cocoa butter NF and tartaric acid NF.

Cafergot® (ergotamine tartrate and caffeine) suppositories are *sealed* in foil to afford protection from cocoa butter leakage. If an unavoidable period of exposure to heat softens the suppository, it should be chilled in ice-cold water to solidify it before removing the foil.

ACTIONS: Ergotamine is an alpha adrenergic blocking agent with a direct stimulating effect on the smooth muscle of peripheral and cranial blood vessels and produces depression of central vasomotor centers. The compound also has the properties of serotonin antagonism. In comparison to hydrogenated ergotamine, the adrenergic blocking actions are less pronounced and vasoconstrictive actions are greater.

Caffeine, also a cranial vasoconstrictor, is added to further enhance the vasoconstrictive effect without the necessity of increasing ergotamine dosage.

Many migraine patients experience excessive nausea and vomiting during attacks, making it impossible for them to retain any oral medication. In such cases, therefore, the only practical means of medication is through the rectal route where medication may reach the cranial vessels directly, evading the splanchnic vasculature and the liver.

INDICATIONS

Cafergot® (ergotamine tartrate and caffeine)

Indicated as therapy to abort or prevent vascular headache, e.g., migraine, migraine variants or so-called "histaminic cephalalgia".

CONTRAINDICATIONS: Peripheral vascular disease, coronary heart disease, hypertension, impaired hepatic or renal function, sepsis and pregnancy.

Hypersensitivity to any of the components.

PRECAUTIONS: Although signs and symptoms of ergotism rarely develop even after long term intermittent use of the orally or rectally administered drugs, care should be exercised to remain within the limits of recommended dosage.

Ergotism is manifested by intense arterial vasoconstriction, producing signs and symptoms of peripheral vascular ischemia. Ergotamine induces vasoconstriction by a direct action on vascular smooth muscle. In chronic intoxication with ergot derivatives, headache, intermittent claudication, muscle pains, numbness, coldness and pallor of the digits may occur. If the condition is allowed to progress untreated, gangrene can result.

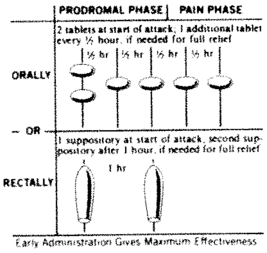
While most cases of ergotism associated with ergotamine treatment result from frank overdosage, some cases have involved apparent hypersensitivity. There are few reports of ergotism among patients taking doses within the recommended limits or for brief periods of time. In rare instances, patients, particularly those who have used the medication indiscriminately over long periods of time, may display withdrawal symptoms consisting of rebound headache upon discontinuation of the drug.

There have been reports of drug abuse and psychological dependence in patients on Cafergot® (ergotamine tartrate and caffeine) therapy. Due to the chronicity of vascular headaches, it is imperative that patients be advised not to exceed recommended dosages with long-term use to avoid ergotism.

ADVERSE REACTIONS: Vasoconstrictive complications, at times of a serious nature, may occur. These include pulselessness, weakness, muscle pains and paresthesias of the extremities and precordial distress and pain. Although these effects occur most commonly with long-term therapy at relatively high doses, they have also been reported with short-term or normal doses. Other adverse effects include transient tachycardia or bradycardia, nausea, vomiting, localized edema and itching.

DOSAGE AND ADMINISTRATION

Procedure: For the best results, dosage should start at the first sign of an attack.



PRODROMAL PHASE
PAIN PHASE
2 tablets at start of attack; 1 additional tablet every ½ hour, if needed for full relief
½ hr
½ hr
½ hr
½ hr
ORALLY
— OR —
1 suppository at start of attack, second suppository after 1 hour, if needed for full relief
1 hr
RECTALLY

Early Administration Gives Maximum Effectiveness

MAXIMUM ADULT DOSAGE

Orally: Total dose for any one attack should not exceed 6 tablets.

Rectally: Two suppositories is the maximum dose for an individual attack.

Total weekly dosage should not exceed 10 tablets or 5 suppositories.

In carefully selected patients, with due consideration of maximum dosage recommendations, administration of the drug at bedtime may be an appropriate short-term preventive measure.

OVERDOSAGE: The toxic effects of an acute overdosage of Cafergot® (ergotamine tartrate and caffeine) are due primarily to the ergotamine component. The amount of caffeine is such that its toxic effects will be overshadowed by those of ergotamine. Symptoms include vomiting, numbness, tingling, pain and cyanosis of the extremities associated with diminished or absent peripheral pulses; hypertension or hypotension; drowsiness, stupor, coma, convulsions and shock. A case has been reported of reversible bilateral papillitis with ring scotomata in a patient who received five times the recommended daily adult dose over a period of 14 days.

Treatment consists of removal of the offending drug by induction of emesis, gastric lavage, and catharsis. Maintenance of adequate pulmonary ventilation, correction of hypotension, and control of convulsions are important considerations. Treatment of peripheral vasospasm should consist of warmth, but not heat, and protection of the ischemic limbs. Vasodilators may be used with benefit but caution must be exercised to avoid aggravating an already existent hypotension.

HOW SUPPLIED

Cafergot® (ergotamine tartrate and caffeine) Tablets

Shell pink colored, sugar coated, imprinted "CAFERGOT" on one side, "S" on other side. Bottles of 250, NDC 0078-0034-28, and cartons of three SigPak® (dispensing unit) packages, each containing 30 tablets in individual blisters, NDC 0078-0034-42.

Cafergot® (ergotamine tartrate and caffeine) Suppositories

Sealed in fuchsia-colored aluminum foil, imprinted "S CAFERGOT® SUPPOSITORY 78-33 SANDOZ". Boxes of 12, NDC 0078-0033-02.

History of Neurology

James Parkinson

On Child Abuse and Other Things

Robert D. Currier, MD, Mary M. Currier, MD, MPH

• James Parkinson, a general physician, was interested in all facets of medical care, and wrote two books for the lay public that contained comments on diverse things. He may have been one of the first physicians to publicly describe child abuse. Some of his advice to the public was of a neurologic nature, and included directions on the diagnosis and treatment of pseudoseizures, epilepsy, drowning, and stroke.

(*Arch Neurol.* 1991;48:95-97)

In his pamphlet, *The Villager's Friend and Physician*, James Parkinson wrote with emotion on child abuse after an encounter in his practice.

> The disease which I shall next speak of is often in its first stage mistaken for the effect of worms. DROPSY OF THE BRAIN, or WATERY HEAD, may be suspected when a child appears uncommonly heavy and dull, complains of pain in the head, has its sleep disturbed with alarming dreams, reluctantly moves its head from the pillow, or attends to surrounding objects; and is affected with frequent sickness and slight fever. . . .[1(p62)]
>
> This complaint is frequently occasioned by the falls on the head which children are exposed to on first going alone. Guard their heads, therefore, at this time, with the old fashioned headdress for children, a quilted stuffed cap, or pudding. I am sorry to be obliged to add another cause of this malady, severe blows on the head, inflicted in the correction of children. Parents too often forget the weight of their hands and the delicate structure of a child. You must excuse the digression—it was but yesterday I passed the cottage of one you all know to have always neglected his children; I heard the plaintive and suppliant cries of a child, and rushed into the cottage; where I saw the father, whose countenance was dreadful, from the strong marks of passion and cruelty which it bore, beating most unmercifully his son, about ten years old. The poor countenance would, one would have supposed, obtained mercy from the most obdurate; it was shrunk up with dread and terror; the most earnest and humble supplications proceeded from his lips, whilst his eyes were fixed with horror on the impending instrument of his chastisement. I stopped the brute from proceeding in his violent outrage, asking what was the crime the boy had committed, and found he had not finished the task of work he had set him. 'Ah, John', I exclaimed, 'consider how you ever neglected your children; you have never troubled yourself to give them good advice nor refrained from setting them bad examples. The crimes of the children of such a parent must be on his head: you merit correction and not he, for you never showed him what it was to be industrious. Expect not duty from a child, if you have not done yours toward him. Duties are required of parents as well as of children; and though an undutiful child may be termed a monster, know that the worst of monsters is an *undutiful parent*.' The wretch growled at the interruption he had suffered; and I need hardly say, manifested no compunction or regret, at his cruelty.[1(p63)]

This must be one of the earliest published comments by a physician on child abuse. Philosophers and writers had proclaimed on it back to biblical times, but did any physician write on it prior to James Parkinson in the year 1800?[2]

In this pamphlet, entitled *The Villagers Friend and Physician; or a Familiar Address on the Preservation of Health, and the Removal of Disease, on Its First Appearance; Supposed to be Delivered by a Village Apothecary. With Cursory Observations on the Treatment of Children, on Sobriety, Industry, etc. Intended for the Promotion of Domestic Happiness* (Fig 1), Parkinson also vented his opposition to wet nursing.

> . . . one more word respecting your children and I have done. Consider it as your first duty to see that your child is not robbed of that food which nature has provided for it in the breast of its mother. Should the mother be tempted for a sordid bribe to transfer to another her child's inestimable right, let her consider, that when she sells the food of her child, she perhaps also sells its life.[1(p83)]

And he concluded the small volume,

> Your next duty is the promotion of your child's happiness. As health is necessary to happiness your watchfulness over him in this respect is indispensable; since by delay, neglect, or ill placed confidence, disease may be so fixed in him as to render him miserable all the rest of his days and even to rob you of him at once. Not less necessary to his happiness is the regulation of even his infant passions and the teaching him to distinguish accurately between right and wrong.
>
> Consider the sacred trust which thus devolves to you, and carefully fulfill this delightful duty. Permit not an unbounded indulgence, lest your child acquire such a disposition, as may be a fruitful source of wretchedness to him and you, and render him odious to all around him. But, on the other hand, exercise the importance privilege of correction with mercy. Contemplate the countenance of the poor child who suffers frequent and severe chastisement; observe every feature contracted by habitual

---

> terror. The most innocent action is performed with alarm and dread. He hardly recovers the shock the system has sustained by one series of suffering, before a fresh series begins. When this is the case, rely upon it the life of that child is iniquitously shortened and the parent is guilty of murdering his child by almost incessant torments.[1(p84)]

Much of Parkinson's general practice must have been pediatrics. He was not above trying original or unusual treatment. In discussing epilepsy in his larger book *Medical Admonitions to Families Respecting the Health and Treatment of the Sick* (1st American edition published 1803) (Fig 2), he also directed the public in health care and mentions the violent gusts of passion that would seize a 7-year-old girl terminating in an epileptic fit. Relief under other physicians was unsuccessful, and finally a friend recommended a remedy that, if done strictly, would always produce a cure. Parkinson gave the prescription as follows:

> Take two ounces of blood about the time of the moon becoming full from the arm of the patient and stir into it a tea spoonful of salt. This mixture must be swallowed while still warm. If the patient experiences any return of the fits the bleeding must be repeated and the blood again drunk on the ninth morning mixed with the salt as before.

Parkinson commented on the success of this remedy.

> The blood was taken away and the horrid potion drank but neither the one nor the other was accomplished without exciting in the unfortunate subject of the experiment the strongest signs of repugnance and horror. Indeed the experiment would not have been made so great a degree of aversion was manifested by the patient had not the parents placed great reliance on a remedy which besides being so strongly recommended was by its uncommoness and by the attention required to be paid to the state of the moon and to certain days well calculated to inspire an extraordinary degree of expectation. Complete success was the reward of their resolution for not only was the return of the fit prevented but a most unexpected event took place, the child was no longer prone to those violent gusts of passion to which she had hitherto been subject.

And he concluded,

> The child could not avoid making the conclusions that to avoid this terrific and disgusting process it was absolutely necessary that she should repress her passionate exertions and that it was much better to submit to the will of her parents than to be again forced to swallow her own blood.[3(p484)]

Parkinson gave very modern sounding instructions about what to do for epilepsy or falling sickness. He recommended that the patient should be protected from injuring himself and therefore should be placed on a bed. The clothing should be loosened and the head moderately elevated. Some substance should be introduced and held between the teeth to prevent their closing on the tongue, but this should not be anything fragile such as earthenware or glass,

> Less from the delirious state which occurs in the interval of the convulsion or from the convulsion itself suddenly coming on he should bite out a piece of the edge of the cup or glass and thereby get the sharpened broken fragments within his mouth.[3(p385)]

In the same volume, Parkinson repeated the directions given by the Royal Humane Society about resuscitation of the drowned. The recommendations were as follows:

> 1. Convey carefully the body with head raised to the nearest receiving house.
> 2. Strip, dry the body, clean the mouth and nostrils.
> 3. Young children to be put between two persons in a warm bed.
> 4. An adult—Lay the body on a bed and in cold weather near the fire.
> 5. The body to be *gently rubbed* with flannel sprinkled with spirits or flower of mustard. The proper substances to be sprinkled on flannels and a heated warming pan, covered, may be lightly moved over the back and spine—Salt never to be employed.
> 6. The breath to be fomented with hot spirits. Hot bricks or tiles, covered, etc. to be applied to the soles of the feet and palms of the hands. If no signs of life appear the body could be put into the warm bath.
> 7. To restore breathing—introduce the pipe of a bellow (when no apparatus is at hand) into one nostril, the other, and the mouth, being closed, *inflate the lungs* until the breast be a little raised; the mouth and nostrils must then be let free. Repeat this process til life appears.
> 8. Tobacco smoke is to be gently thrown into the fundament, with a proper instrument, or the bowl of a pipe covered so as to defend the mouth of the assistant.
> 9. Electricity to be early employed either by the medical assistants, or other judicious practitioners.[3(p377)]

After more instructions for various other causes of unconsciousness the conclusion was that "the plans of resuscitation are to be used for three or four hours" and "it is an absurd and vulgar opinion to suppose persons irrecoverable because life does not soon make its appearance." And finally, "bleeding never to be employed unless by the direction of the medical assistants."[3(p380)]

So, in Parkinson's time, public recommendations included the employment of artificial means to restore breathing, a recommendation that was later to be forgotten and only in the past few decades rediscovered.

Who was James Parkinson? He was a practicing physician at One Hoxton Square in Shoreditch in northeast London, as was his father before and his son after him. A busy man with a wife and five children he was involved in church work and strongly interested in politics, especially liberal causes and, in fact, dangerously involved in politics in the first half of his life. He wrote political pamphlets under the pseudonym Old Hubert and was accused of playing a part in the popgun plot against George III. Clear thinking and logical, he disliked dishonesty and the incorrectness of things as they were then and tried to stimulate reforms. He also was the author of one of the first comprehensive textbooks on fossils in the English language, wrote a pocket textbook on chemistry and one on gout, and was not above suggesting that medical education reforms were in order in another book. It would have been hard to know which area interested him the most at any one phase in his life.

Certainly he was gifted with the pen. McMenemey,[4] who wrote a comprehensive biography, comments that his sentences were long and involved and yet could be clearly understood, either the result of a unique gift or careful thought in writing, or both. The two books quoted here were designed for the lay public and must have been among the first such books in English.

Of course his *Essay on the Shaking Palsy* is one of the finest descriptions of disease of all time, but he also commented on other neurological events. In the same two volumes he distinguished between apoplexy and palsy. Apoplexy:

> In this disease, the whole of the senses, and of the voluntary motions, are in some degree abolished whilst the actions of the heart and lungs continue. The appearance of the patient is that of one in a deep sleep; the breathing being mostly accompanied by a loud snoring.[3(p352)]

He did not recognize that he was describing intracerebral hemorrhage, but did recommend bleeding for apoplexy and not for palsy. Palsy could occur in those who had had apoplexy

> Such persons as have been already described, in the preceding chapter, as predisposed to attacks or apoplexy, are also very liable to paralytic affections.[3(p366)]

Furthermore, he recognized that sometimes symptoms occurred before the apoplectic attack.

> Sometimes this disease comes on suddenly; but most frequently it is preceded by these symptoms. The face for sometime before appears more than usually florid and the eyes slightly bloodshot. The head is giddy and frequently affected with pain, particularly in the back of it. The extremities also are frequently affected with numbness, and irregularities, or inability of motion; and sometimes a little faltering of speech may be discoverable. The patient is almost constantly drowsy, and generally sleeps particularly sound; but is sometimes affected with fits of the *incubus* or nightmare. A troublesome ringing noise is frequently perceived in the ears; transient irregularities both in sight and hearing are frequently discovered, and every sense appears at times to be somewhat impaired. Recollection, reflection and every other process of the mind, is performed evidently with lessened power.[3(p353)]

Was Parkinson also the first person to describe transient ischemic attacks? He commented on risk factors:

> The subjects of the disease are generally persons in an advanced stage of life. Those who have been observed to be particularly disposed to it, who are of a corpulent habit, and have a large head and short neck. Indolence, and indulgence in the luxuries of the table, as well as the suppression of any discharge which by its length of continuance has been suffered to have become habitual to the constitution, contribute much to the forming of a predisposition of this disease.[3(p353)]

He later said that anything that interrupts the return of blood from the head may prove an exciting cause of apoplexy, as may violent exertion, especially if accompanied by full and long continued inspiration, a considerable degree of fatigue, excessive heat or cold, violent coughing, long-continued stooping posture or with the neck in an oblique position, anything worn tight about the neck, intoxication, distention of the bowels, and violent emotions. Under palsy he mentioned in addition that extreme coldness and dampness of the atmosphere play a part since the attacks are more frequent at the first setting in of winter, occur in those who lead sedentary lives and are engaged in night studies, those who suffer much distress and anxiety, and the immoderate use of spiritous liquors, tobacco, coffee, and tea will be likely to promote the production of the complaint.[3(p366)]

Parkinson even recommended certain therapies. "Exercise should be regularly employed." But electricity is not advisable, it might actually make the palsy worse.

The list of those who have written on Parkinson starts with Rowntree's tribute in 1912, in which he very carefully summarized the prior writings.[5] The most extensive biographies are those of McMenemey in 1955[4] and the recent book by Morris in 1989,[6] for which we can thank Clifford Rose who saved the manuscript from oblivion after Dr Morris' death. Comments by others, including Williamson,[7] Eyles,[8] McHenry,[9] Schulte,[10] and Jefferson,[11] have been added over the years, and Yahr,[12] Richard and Kenneth Tyler,[13] Pearce,[14] and Herzberg[15] have more recently kept the torch alight for the man. We thought it worthwhile to recall from these two relatively unknown books some of his two-century-old recommendations in pediatrics, general practice, and neurology that have not heretofore been publicly acknowledged, and to suggest he may have been the first physician to comment on child abuse.

The American Neurological Association

The American Neurological Association Call for Papers

The 116th Annual Meeting of the American Neurological Association will be held at the Sheraton Hotel, Seattle, Washington, beginning at 8:30 AM Monday, September 30, and ending at 1:00 PM Wednesday, October 2, 1991.

1. Authors need not be members of the American Neurological Association nor be sponsored by a member. All are welcome to submit abstracts. Acceptance will be based entirely upon quality, without consideration as to status of membership in the ANA or type of presentation. Poster sessions will be expanded; therefore posters are encouraged.
2. An abstract, not exceeding 200 words in length, double-spaced, should be submitted to the Program Chairman. *Deadline for receipt of abstracts is March 1, 1991.* Please spell out all abbreviated terms at first use or, if many abbreviations are used, attach a separate sheet listing spelled-out abbreviations. No continuation page, illustrations, or tables are to be included. An original and 10 copies must be submitted. Abstracts must report work not presented or published prior to the meeting. Additional forms may be photocopied.
3. Abstracts are solicited on the following topics:
   A. Behavioral Neurology
   B. Cerebrovascular Disease
   C. Dementia and Aging
   D. Degenerative Diseases
   E. Epilepsy
   F. Headache and Pain
   G. Movement Disorders
   H. Neuromuscular Disease
   I. Neuroscience
   J. Neuroimmunology
   K. Neurooncology
   L. Neuroophthalmology
   M. Neuropharmacology
   N. Pediatric Neurology
   O. Rehabilitation, Regeneration and Recovery
   P. Neurovirology
   Q. Trauma/Injury
   R. Other

   Authors are asked to indicate the specific topic in the box provided on the abstract form. Please use the *letter* designation.
4. The time allowed for presentations from the platform and posters may vary according to the material presented and needs of the session. Authors will be notified by the chairperson.
5. *Annals of Neurology* is the official journal of the American Neurological Association. All papers presented at the annual meeting must be submitted to the Editor for consideration by the Editorial Board of the *Annals*. Authors not wishing to have their papers considered by the *Annals* must obtain a release in writing from the Editor before submitting them for publication elsewhere.

Send abstracts and correspondence to:

Observations

Anton's Syndrome in a Patient With Posttraumatic Optic Neuropathy and Bifrontal Contusions

Keith D. McDaniel, MD, Leslie D. McDaniel, MD

• We describe a patient who manifested Anton's syndrome after sustaining head trauma that resulted in optic nerve damage and bifrontal contusions. Denial of monocular blindness, generalized anosognosia, and confabulation were prominent neurobehavioral features. Anton's syndrome is most commonly encountered in patients with bilateral occipital cortex lesions. Patients previously described who demonstrated Anton's syndrome secondary to a peripheral lesion have had an associated delirium or profound dementia. Our case demonstrates that Anton's syndrome may occur in association with blindness from a peripheral lesion, even in the absence of a delirium or significant dementia. We suggest that the bifrontal dysfunction may have been a critical factor in the production of Anton's syndrome. Implications for the role of frontal lobe dysfunction in the genesis of anosognosia and confabulation are discussed.

(*Arch Neurol.* 1991;48:101-105)

Anton's syndrome traditionally refers to the clinical phenomenon of denial of blindness in a patient who has suffered acquired cortical blindness.[1-5] The most common setting of Anton's syndrome is acute bilateral occipital cortex ischemia secondary to posterior circulation insufficiency.

Anton's syndrome is best classified as a subtype of anosognosia, a term originally introduced by Babinski[6] to describe nonrecognition of a specific neurologic deficit. Early descriptions of anosognosia referred primarily to nonrecognition of left hemiplegia in patients with right hemispheric damage.[6-8] Later, anosognosia took on a broader definition to include nonrecognition or denial of hemiplegia, paraplegia, involuntary movements, amnesia, and blindness.[9-18] The degree of anosognosia ranges from minimization of a specific deficit, indifference, or unconcern to lack of recognition and frank denial.

Not all patients with acquired cortical blindness deny their deficit, and there is debate concerning the pathoanatomic locus and neurobehavioral features associated with denial of blindness. Because of its classification as a type of anosognosia, and its occasional co-occurrence with left hemiplegia,[12,19] some investigators have intimated that the anatomic substrate for Anton's syndrome may be the same as for other anosognosias.[12,14] Specifically, the most common and persistent of the anosognosic syndromes are associated with large right hemispheric lesions, producing denial of left hemiplegia, and some authors have suggested that the anosognosic component of cortical blindness may be secondary to right hemispheric dysfunction[20] or to disruption of thalamic connections to right parietal association cortex or visual association cortex.[7,14,20] Others[21] have stated that denial of blindness results when occipital cortex lesions extend beyond calcarine cortex to include visual association cortices (Brodmann's areas 18 and 19).

Disorders of recent memory[18,22,23] are frequently observed in patients with Anton's syndrome. Because cortical blindness is often secondary to posterior circulation insufficiency, inferomedial temporal lobe structures can be similarly affected, thereby producing a disorder of recent memory. The observation that patients with Anton's syndrome confabulate about their visual deficit as well as events subserved by recent memory[13,18,19,22,23] suggests that these patients may also have anosognosia for their memory deficit, thereby resembling patients with Korsakoff's syndrome.[13,23]

Anton's syndrome classically occurs with cortical blindness, and was believed not to occur in cases of blindness from peripheral causes.[24] Although the syndrome is most commonly described in patients with cortical blindness,[1,12,19,21,25-29] there have been numerous case reports of Anton's syndrome occurring in patients with lesions to the anterior visual system, including anterior chamber, optic nerve, and optic chiasm.[13,18,30-34] In all cases of Anton's syndrome associated with anterior visual system lesions, except perhaps one,[22] there has been evidence of profound diffuse cognitive dysfunction.[13,18,30-34] These patients are described as demonstrating evidence of "coarse brain disease" including significant clouding of consciousness, confusion, disorientation, and/or severe dementia. These clinical observations suggest that different mechanisms may be operating in the production of denial of blindness depending on which part of the visual system has been damaged. Geschwind[18] has suggested that when blindness is secondary to a peripheral lesion, denial of the deficit is more dependent on clouding of consciousness or marked dementia than in Anton's syndrome secondary to central lesions, in which damage to visual association cortex is involved.

We report a case of Anton's syndrome in a patient who sustained head trauma with bifrontal contusions and traumatic optic nerve damage that resulted in monocular blindness. Although some memory impairment was present, at the time of the patient's denial of blindness she evidenced neither a confusional state nor a significant dementia. In this case, the denial of blindness was closely correlated with a more generalized anosognosia and a marked propensity for confabulation.

REPORT OF CASE

A 36-year-old right-handed woman was hospitalized after being hit by a subway, having sat in front of the oncoming car in a suicide attempt. She had a history of de-

pression and alcohol and benzodiazepine abuse, but no known history of psychotic symptoms or cognitive impairment. The patient sustained an open, depressed, right anterior frontal skull fracture, multiple maxillary and ethmoid fractures, a right orbital blowout fracture, and pelvic and right lower-extremity fractures. She had initially been found unconscious, but on admission was awake and alternately lethargic and combative, disoriented to place, inconsistently able to answer simple questions, and able to follow only simple commands. Her vital signs were stable. Neurologic examination on admission revealed complete ophthalmoplegia of the right eye with minimal exodeviation; the right pupil was dilated (8 mm), without direct or consensual response to light. Visual acuity examination of the right eye revealed no light perception, and the patient did not respond to visual threat. Examination of the left eye revealed intact direct pupillary light response, visual acuity, and extraocular movements, but absent consensual pupillary light response. The patient was able to move all extremities to command, and plantar responses were flexor.

The blood alcohol level on admission was 157 mg/dL, and the remainder of the toxicology screen was negative.

Computed tomographic head scan on admission demonstrated bilateral frontal fractures extending into the right maxillary sinus and cribriform plate and into the frontal and ethmoidal sinuses bilaterally. There was a fracture through the medial wall of the right orbit, with multiple bone fragments in the right orbit noted near the optic nerve, which appeared edematous. Bilateral hemorrhagic frontal contusions were evident.

The day of admission the patient underwent a craniotomy with subtotal evacuation of bifrontal hematomas, removal of bone fragments, dural repair, and elevation of the depressed skull fracture. Postoperative computed tomographic scans (Figs 1 through 8) showed bilateral frontal contusions with edema, fracture of the right sphenoid wing, and multiple maxillary sinus, right medial orbital, nasal, and frontal fractures. There was evidence of clinoid and posterior sphenoid fractures at the right optic canal and possible hemorrhage or a bone fragment in the right optic nerve.

During postoperative days (PODs) 2 through 7, the patient was awake, intermittently agitated and lethargic, and able to follow simple commands, but no formal mental status testing was performed. She was treated with morphine sulfate (40 to 80 mg/d), midazolam (10 to 35 mg/d), diphenhydramine hydrochloride (50 mg/d), and phenytoin (300 mg/d). Her neurologic examination revealed ophthalmoparesis of the right eye, a right afferent pupillary defect, and no demonstrable vision in the right eye. The right-sided blindness was thought to be secondary to compression or transection of the right optic nerve; and the ophthalmoparesis, to retro-orbital edema. Right ophthalmoparesis was present until POD 8, when full eye movement returned.

On POD 8, psychiatric consultation was requested because of agitation and increasingly disorganized and impulsive behavior. The patient had had tachycardia over the previous several days, but her blood pressure was normal and there was no tremor or nystagmus. On mental status examination, the patient was oriented to year and month but not to day or location. She was distractable and had decreased ability to focus attention (digit span: five forward and none in reverse). Recent memory was impaired, as judged by her inability to recall any of four words after 5 minutes. Language was fluent but disorganized with marked perseveration and confabulation. The patient stated that she was at her sister's house and when confronted with evidence of the hospital surroundings, replied: "Oh, that peroxide and needles are my sister's. She has a skin problem...." She spontaneously reported previous fictitious conversations with staff members. Although both her legs were in casts and her right leg was in traction, she completely denied any problems with her legs. The patient was not fully cooperative with cognitive testing; however, the most prominent aspects of her examination were the disturbance of recent memory; striking spontaneous confabulation about her environment, relationships to hospital staff, and her injuries; and complete denial of all aspects of her illness. The magnitude of these abnormalities were out of proportion to her attentional deficit.

Although the neurobehavioral examination suggested bifrontal and temporal dysfunction, there was evidence of a component of mild delirium, presumed secondary to multiple factors including post-head trauma, postcraniotomy, and morphine and/or benzodiazepine intoxication. Over the next 2 days, with a decrease in the morphine sulfate dosage from 80 mg/d to 6 to 10 mg/d, and discontinuation of midazolam, the patient's agitation, disorientation, and attentional disturbance decreased markedly. On POD 11, the patient was oriented to the date, city, and hospital, but she confabulated about the specific name of the hospital. Her attention span was improved (six digits forward and three in reverse). Language examination revealed normal comprehension, repetition, and naming, but decreased word fluency (word-list generation: five animals in 1 minute). Ideomotor praxis, double-digit calculations, and constructional ability were intact. Recent and remote verbal memory remained impaired. Her interpretations of idioms and proverbs were concrete. Her ability to do frontal motor tasks (Luria hand sequence, alternating sequences, and reciprocal programs) was impaired. She showed paranoid ideation, thinking that the nursing staff was attempting to harm her. Neurologic examination revealed no paresis, symmetric testable reflexes, and normal sensory examination, with no extinction to double simultaneous tactile stimulation. The results of the visual acuity examination were unchanged from POD 8, and continued to show that the patient had no light perception or response to visual threat in her right eye.

At this time (POD 11) the patient continued to demonstrate denial of her illness and prominent confabulation. Although she was blind in her right eye (on six separate trials of varying numbers of fingers held up to each eye separately with the opposite eye occluded, the patient answered six times incorrectly on the right and six times correctly on the left), she denied the visual defect. She offered erroneous answers, stating that she could see, and gave numerous excuses for mistakes made (lighting, headache, angle of the bed; eg, "No, I can see it. I just have a headache...."). She also continued to deny other aspects of her illness. For example, when asked about her leg sling, she replied: "That's not a leg sling, that's an outfit for work; it's a cape. There's nothing wrong with that leg.... I'm in the hospital for a miscarriage.... It's nothing really visible. The doctors are just trying to compare the two legs."

On POD 14, vision in the right eye improved, with evidence of some light perception and accurate finger counting in the superior field of the right eye. At this time the patient began to acknowledge her visual deficit stating, "I can't see very well in that eye." Her recent memory also appeared improved at this time (one out of three words recalled after 5 minutes). Denial of her illness and confabulation about her relationships with staff members and her medical condition continued but were less marked. Over the next 2 weeks her recent memory deficit, denial of illness, and confabulation gradually resolved. By POD 30, the patient demonstrated full orientation and normal attention and concentration abilities. Her long-term memory was improved, and her visual and recent verbal memory were intact (able to recall three out of three words after 5 minutes). She demonstrated good verbal comprehension, naming, and repetition but continued to show decreased word fluency (six animals in 1 minute). Constructional ability and calculations were intact. Although the frontal motor tasks were accurately performed, her thinking remained concrete. She only rarely confabulated about her relationships with staff members.

The behavioral syndrome described on POD 11 persisted and included inappropriate, disinhibited behavior with evidence of poor insight and social judgment, extreme irritability, affective lability, verbal disinhibition with frequent threats and occasional physical abuse toward nursing staff, and paranoid ideation. The patient's family stated that these behaviors had not been present at any time prior to the hospitalization.

On POD 42, computed tomographic head scan showed bifrontal encephalomalacia with increased size of the anterior horns of the lateral ventricles and a questionable bone fragment extending into the superior aspect of the right orbit. Electroencephalography showed normal alpha activity posteriorly, with intermittent bilateral temporal and posterior temporal slowing in the theta and, at times, delta frequencies.

COMMENT

This is the first detailed published case of Anton's syndrome associated with blindness from an anterior visual

Figs 1 through 8.—Postoperative noncontrast computed tomographic head scan performed the day of admission demonstrating bilateral frontal contusions, disruption of the integrity of the right optic foramen from posterior sphenoid fractures (arrow, Fig 1), and possible hemorrhage or bone fragment adjacent to right optic nerve (arrowhead, Fig 2). Figure 1. Figure 2. Figure 3. Figure 4. Figure 5. Figure 6. Figure 7. Figure 8.

lesion occurring in the absence of a confusional state or significant dementia. Stuss and Benson[22] reported a remarkably similar case of bifrontal contusions and blindness from optic neuropathy, with unconcern and minimization of the visual deficit. Their brief description stated that the patient was "alert and fully oriented"; however, more detailed neuropsychological testing was not reported. The patient we describe demonstrated numerous neurobehavioral abnormalities, including an orbitofrontal lobe syndrome (disinhibited, impulsive behavior, inappropriate affect, emotional lability, irritability, poor judgment and insight, distractibility, and unconcern),[35] impaired frontal motor tasks, verbal memory disorder, confabulation, and denial of illness, including Anton's syndrome. Language (except for diminished word-list generation), ideomotor praxis, visuoconstructive and calculation abilities, and visual memory were all unaffected. At the time the patient manifested Anton's syndrome, findings of the elementary neurologic examination were normal, with the exception of the noted blindness of the right eye and the absence of right direct pupillary response.

Two prominent features of the current case are the patient's generalized anosognosia and the dramatic spontaneous confabulatory responses, which persisted beyond the acute confusional state. Although confabulation is most often encountered in the acute stages of Korsakoff's syndrome,[36] it is also seen in patients with amnesia resulting from a variety of causes.[35] As not all patients with amnesia demonstrate confabulation, a concomitant neurobehavioral alteration or focal anatomic lesion may be necessary for the production of confabulation. Although some degree of memory impairment is probably necessary, there is evidence that confabulation is additionally dependent on frontal lobe dysfunction manifesting as perseveration, lack of verbal inhibition, and poor self-monitoring.[37-39] Some investigators have speculated that the confabulation demonstrated by patients with Korsakoff's syndrome is an indication of impairment of cognitive functions in addition to memory.[40] The poor strategy formation in problem-solving tasks demonstrated by these patients[41] suggests disruption of frontal lobe functioning. The bulk of evidence indicates that confabulation is encountered most commonly in patients with memory disorders when there is an associated confusional state or bifrontal dysfunction.[38,39,42-44] Some investigators distinguish between provoked confabulation as a normal response to impaired memory and spontaneous or fantastic confabulation as indicative of frontal dysfunction occurring in conjunction with an underlying memory disorder.[38,43,44] Additionally, there is speculation that deficits in frontal lobe-dependent, self-monitoring functions may also be involved in producing anosognosic syndromes.[22]

Many observers have noted a close relationship between the tendency toward confabulation and anosognosia.[5,18,22,23,40] The intricacies of these phenomena have recently been elaborated by Fisher,[23] who suggests that "unawareness is a necessary precondition for confabulation." Importantly, in virtually all cases of both central and peripheral Anton's syndrome described, there is mention of confabulation, in relation both to the visual deficit itself and to other aspects of the patient's clinical state.[13,18,19,21,25] In our patient, confabulation was closely associated with generalized anosognosia, both of which resolved almost simultaneously. It may be that confabulation is a requisite accompaniment to Anton's syndrome regardless of the site of visual system damage.

Our patient demonstrated a memory disorder with electroencephalographic evidence of bitemporal dysfunction and a clinical frontal lobe syndrome with bifrontal structural lesions demonstrated on computed tomographic scan. We suggest that the bitemporal and bifrontal dysfunctions were essential in the production of the patient's confabulation and anosognosia and that these features, in conjunction with the visual defect, produced Anton's syndrome. The patient's memory disorder, confabulation, and anosognosia resolved together, although the frontal lobe behavioral syndrome persisted. With regard to the patient's anosognosia, it is important to note that right parietal function was found to be normal based on visuoconstructive abilities, neurologic examination, computed tomographic scan, and electroencephalography.

As noted in the case description, resolution of the denial of monocular blindness occurred as the patient's vision began to return. The remaining anosognosic features persisted and then subsequently cleared with resolution of the confabulation and memory disorder, suggesting an important interaction among these variables. However, it is important to note that the anosognosia and confabulation occurred when edema from the acute frontal contusions would have been maximal. Independent of improvement of the patient's memory function, it is possible that reduction of frontal edema was a contributing factor in the resolution of both the confabulation and the anosognosia.

This case demonstrates that denial of blindness in cases of anterior visual system lesions does not necessarily require a confusional state or severe dementia, as suggested in previous reports. Instead, we suggest that the interaction of a memory deficit with the inability to critically self-monitor responses due to frontal dysfunction was sufficient to produce denial of blindness secondary to a peripheral lesion. This case provides supporting evidence for the hypothesis perhaps initially proposed by Bychowski[45] and elaborated by Stuss and Benson[22] that frontal lobe dysfunction may be a critical factor in nonrecognition or denial of a deficit, including blindness resulting from peripheral causes.

Pupil-Sparing Oculomotor Nerve Palsy due to Midbrain Infarction

Lenore A. Breen, MD; Hanns C. Hopf, MD; Bradley K. Farris, MD; Ludwig Gutmann, MD

• Vasculopathic oculomotor nerve palsies with pupillary sparing are thought to be due to ischemic damage to the nerve in the subarachnoid space or the cavernous sinus. We present two cases of patients with isolated pupil-sparing oculomotor nerve palsies due to midbrain infarcts. Focal ischemic midbrain lesions should be considered in cases of pupil-sparing oculomotor nerve palsies.

(*Arch Neurol.* 1991;48:105-106)

Infarction of the oculomotor nerve causes pupil-sparing oculomotor palsies associated with diabetes mellitus or hypertension. At present, the favored site of the infarction is the peripheral portion of the nerve, rather than the intra-axial portion. Intra-axial lesions causing pupil-sparing oculomotor palsies are rare in the literature.[1] The association of a hemiparesis, rubral tremor, or sensory loss with the oculomotor palsy places the lesion in the midbrain. In 1987, Hopf and Gutmann[2] postulated the intra-axial location of isolated pupil-sparing palsy based on studying the masseter reflex. The mesencephalic tract of the trigeminal nerve moderates the masseter reflex. This tract extends up to the level of the oculomotor nucleus and lies dorsolateral to the nucleus. The authors hypothesized that a lesion affecting the oculomotor nerve in the midbrain also could affect the masseter reflex. Using electrophysiologic recording of masseter reflex responses, they found depressed responses ipsilateral to the oculomotor palsy in several patients. In support of this hypothesis, we report two cases of patients with isolated pupil-sparing oculomotor palsy with magnetic resonance imaging scan substantiation of mesencephalic lesions.

REPORT OF CASES

Case 1.—A 23-year-old previously healthy woman presented with the abrupt onset of severe, throbbing retro-orbital headache on the left side. An hour later, she noticed oblique diplopia and ptosis of the left eyelid. Prior to reaching the hospital, she experienced tingling around the mouth on the right side associated with slurred speech and clumsiness of her right hand. By the time she reached the emergency department, the paresthesias and dysarthria had resolved. Her medical history was unremarkable except for the use of oral contraceptive agents for 2 years. The family history was positive for migraine in her mother and maternal grandmother.

Examination on admission revealed only a complete oculomotor palsy with total sparing of the pupil. No speech disturbance or other focal neurologic signs were evident. Results of radiologic studies, including a computed tomographic scan of the head with and without contrast, and cerebral angiography of the carotid and basilar arterial systems were normal. Results of blood tests revealed negative serologic test results for syphilis, a Westergren sedimentation rate of 15 mm/h, a negative antinuclear antibody and rheumatoid factor, and normal complement function. Screening for diabetes, hypertension, and heart disease was also negative. The spinal fluid was normal with a cell count of 4×10^6 leukocytes per liter and 5×10^6 erythrocytes per liter. The cerebrospinal fluid protein level was 0.28 g/L and the glucose level was 2.9 mmol/L. Cerebrospinal fluid VDRL was negative, and the IgG levels, myelin basic protein, and oligoclonal bands were all within normal limits. Results of an edrophonium test were also negative. A magnetic resonance imaging scan revealed a lesion in the left midbrain suggestive of an infarct (Fig 1). The abnormal signal was located primarily in the fascicular portion of the left third nerve in the caudal portion of the midbrain. The diagnosis of complicated migraine was made. She stopped taking her oral contraceptives and had gradual improvement of her ptosis and ocular motility, with total resolution after 6 months. No evidence of acquired oculomotor synkinesis was present at the time.

Case 2.—A 78-year-old woman with insulin-dependent diabetes mellitus presented with the painful abrupt onset of horizontal diplopia. Examination revealed a complete third-nerve palsy of the left eye with total sparing of the pupil. A computed tomographic scan of the head was normal. The magnetic resonance imaging scan revealed a lesion in the left midbrain in the fascicular portion of the third nerve (Fig 2).

Masseter reflex latency (3 days after onset) was determined by stimulating the jaw mechanically with a reflex hammer containing a piezo-electric element to trigger the oscilloscope sweep. The reflex response was recorded simultaneously by surface electrodes over both masseter muscles (recording electrodes) and the lateral edge of the orbits (reference electrodes). The reflex latency was 8.7 milliseconds on the left side and 7.9 milliseconds on the right side (normal side-to-side difference, <0.5 milliseconds). Two weeks later the latencies were normal at 8.1 milliseconds bilaterally.

COMMENT

Both of our patients had apparent ischemic pupil-sparing oculomotor

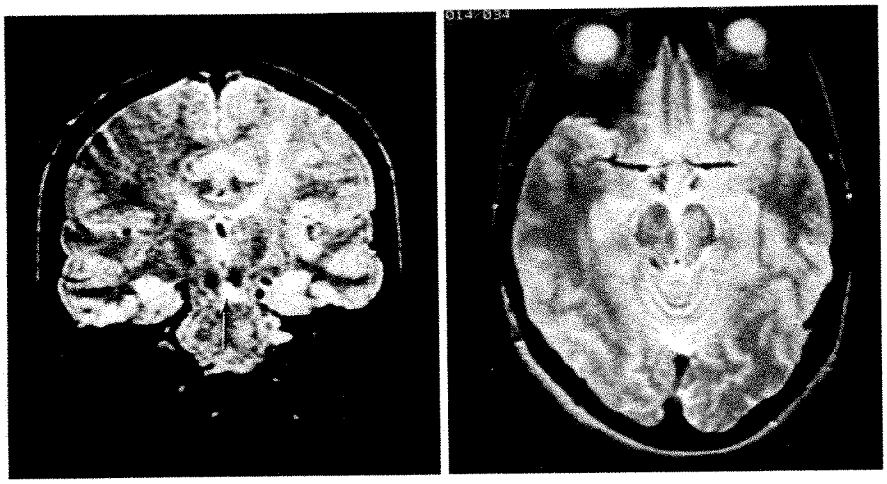

Fig 1.—Left, Case 1. Coronal T_2-weighted magnetic resonance imaging reveals an area of increased signal in the midbrain located left of the midline and caudal to the red nucleus. Right, Case 1. Axial T_2-weighted magnetic resonance imaging reveals an area of increased signal on the left in the region of the third-nerve fascicle.

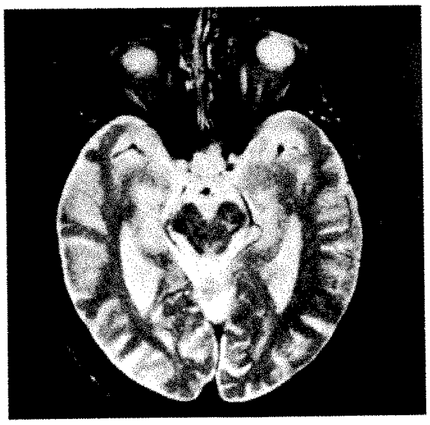

Fig 2.—Case 2. Axial T_2-weighted magnetic resonance imaging at the midbrain level reveals an area of increased signal on the left side adjacent to the cerebral peduncle extending into the third-nerve fascicle.

palsy unassociated with other neurologic abnormalities on examination, and had demonstrable midbrain lesions by magnetic resonance imaging. The prolonged masseter reflex latency in patient 2 also supports an intra-axial lesion. These cases challenge the present tenets regarding isolated pupil-sparing oculomotor lesions of ischemic origin. Three autopsy studies of diabetic patients with pupil-sparing oculomotor palsy provide the basis for the current theory about the location of the anatomic lesion.[3-5] Examination of the affected nerves revealed abnormalities in the cavernous sinus portion of the nerve,[3,4] or just after exiting the midbrain in the subarachnoid space.[5] Microscopic sections revealed destruction of myelin, narrowing of the vasa nervorum, and axonal damage. None of the autopsy studies found the arterial occlusion thought to casue the lesion. The authors found sparing of the peripherally located pupillomotor fibers in comparison with the core of the nerve. They felt that pupillary sparing was based on end-arterial ischemia to the center of the nerve and the relative resistance of the small unmyelinated pupillary fibers to ischemia.

In our cases the lesions diagnosed by magnetic resonance imaging are in the fascicular portion of the nerve. The fibers of the oculomotor nucleus traverse the midbrain as multiple bundles and course both through and around the red nucleus.[6] The expansion of the red nucleus during embryologic development is thought to cause the spreading of the fibers. Neuroanatomic studies of rats show that the oculomotor rootlets emerge from the brain stem as free rootlets and fuse to become the oculomotor nerve trunk after traveling a short distance in the subarachnoid space.[7] Therefore, a fascicular lesion could theoretically lead to sparing of the pupil or an innervated muscle. In addition, the caudal location of the lesion in patient 1 could explain the pupil sparing by not involving fibers from the more superiorly located Edinger-Westphal nucleus. Fascicular lesions of the oculomotor nerve have caused other atypical oculomotor palsies.[1,8,9] In 1983, Nadeau and Trobe[1] published two cases of pupil-sparing oculomotor palsy due to midbrain lesions involving the fascicle. These cases differed from ours in that both of the patients had additional neurologic findings on examination.

Oculomotor nuclear lesions also cause atypical partial oculomotor palsies. In 1982, Warren et al[10] reported cases of isolated inferior rectus palsies. The authors felt the anatomic lesion was in the oculomotor nucleus. Smith[11] questioned the validity of the hypothesis because no anatomic proof was available. Five years later an autopsy study of a patient with an isolated inferior rectus palsy revealed a solitary metastasis to the apropriate oculomotor nucleus.[12] Magnetic resonance imaging scans revealed the lesion premorbidly.

Focal midbrain lesions can be the basis for isolated pupil-sparing oculomotor palsies, and may be more common than previously thought. Hopf and Gutmann,[13] studying diabetic patients with isolated third-nerve palsies (the majority with pupil sparing), noted that the ipsilateral masseter reflex response was completely or partially absent or the reflex latency was delayed in most of the patients. These findings provide further support for a mesencephalic location for isolated oculomotor palsies. Continuing investigations involving magnetic resonance imaging scans, pathologic examination, and electrophysiological studies are needed to further assess the relative importance of midbrain lesions in the cause of these cases.

Congenital Monomelic Hypertrophy With Progressive Myopathy

Amitabh Shukla, MD; Colin D. Hall, MD; Walter G. Bradley, DM, FRCP; William W. Pendlebury, MD

• We describe a patient with congenital monomelic hypertrophy who later developed progressive footdrop due to a degenerative myopathy. The clinical, electrophysiologic, and pathologic features of the case are described and compared with those of a previously reported case.

(*Arch Neurol.* 1991;48:107-110)

From the earliest investigation of progressive degenerative disorders of muscles in the mid-19th century, there has been interest in the phenomenon of muscular hypertrophy, or pseudohypertrophy.[1-3] This is usually a symmetrical and generalized process, and associated with progressive muscle weakness. There have been a small number of reports of muscle hypertrophy associated with nerve lesions, such as radiculopathies,[4-6] but usually muscle weakness with hypertrophy (pseudohypertrophy) is a myopathic process. There have also been a few reports of congenital hypertrophy of muscle, connective tissue, and bone restricted to one side or to a single extremity[7-16] and associated with diverse clinical features. One patient with monomelic hypertrophy described by Celesia et al[7] developed a progressive myopathy. We report a second case of congenital monomelic hypertrophy with progressive myopathy, which differs from the case reported by Celesia et al[7] because of the absence of clinical and electromyographic myotonia.

REPORT OF A CASE

At birth, the left leg of our patient was noted to be larger than the right, both in girth and in length. At the age of 11 years, she underwent epiphysiodesis of the left fibula, tibia, and second and third toes and ray deletion and excision of the fifth toe. A biopsy specimen of the tibialis anterior muscle showed chronic myopathic changes (see below). The specimen of the left fifth toe included muscle that showed no abnormality. Soon after this, her parents noted that she had difficulty with the frog kick while swimming, and at the age of 12 years, she developed inability to dorsiflex the left great toe. At the age of 15 years, she underwent a left peroneus longus tendon transplant and debulking and shortening of the first and second toes. A left adductor hallucis muscle biopsy specimen showed chronic myopathic changes similar to those seen in the tibialis anterior muscle specimen. At age 16 years, the patient developed a progressive left footdrop and underwent electrophysiologic studies (see below), computed tomography, and magnetic resonance imaging of the thoracolumbar region, all of which revealed no abnormalities. By the age of 20 years, the left footdrop had progressed, and the patient complained of left hip and leg pain on walking. Subsequent electrophysiologic studies and magnetic resonance imaging of the legs were performed (see below).

A physical examination performed when the patient was 20 years old showed her left leg to be 1 inch longer than her right leg. The circumference of the left leg and the size of the left foot were increased compared with the right (Fig 1). Her left shoe was size 8, and her right shoe was size 6. The muscle bulk was increased throughout the left leg, with the exception of the left tibialis anterior muscle, which was of normal bulk. There was no hypertrophy of any other parts of the body. There was a left footdrop with varus deformity and contracture of the left tendo achillis. There was no observable contraction of the left tibialis anterior, peroneus longus, and extensor hallucis longus muscles. The left triceps surae muscle, hip adductors and abductors, and extensor digitorum brevis muscle were slightly weak on toe walking. The strength of all other muscles appeared normal. The right knee and ankle jerks were 2+, the left knee jerk was trace, and the left ankle jerk was 1+. Plantar responses were flexor. There was diminution of pinprick sensation over the upper lateral aspect of the left shin that had been present since the prior knee surgery.

INVESTIGATIONS

The patient's serum creatine kinase level was 165 IU (normal, 21 to 80 IU), with an MB fraction of 7% and a BB fraction of 0%. Other hematologic and biochemical test results were normal.

Peripheral Electrophysiologic Studies

When the patient was 16 years old, findings of motor conduction studies in the left peroneal nerve, terminal latency, F-wave latency, and amplitude of the maximal evoked-action potential were normal, as was the left sural sensory nerve action potential.

Electromyography (EMG) of the left tibialis anterior muscle showed profuse fibrillation potentials and positive sharp waves, complex repetitive discharges (CRDs), and numerous early-recruited brief-duration motor unit action potentials. Similar but lesser changes were seen in the left peroneus longus and vastus lateralis muscles. The left gastrocnemius muscle, the muscles in the right lower limb, and the paraspinal muscles showed no abnormalities. Single fiber EMG of the left tibialis anterior muscle revealed an increased fiber density of 2.05 (normal, 1.57 ± 0.22),[17] with several pairs exhibiting increased jitter and blocking.

When the patient was 19 years old, findings of motor conduction studies in the left peroneal and tibial nerves were entirely normal, including peroneal nerve conduction across the fibular head. Electromyography of the left tibialis anterior and extensor hallucis longus muscles showed increased insertional activity, fibrillation potentials and positive sharp waves, CRDs, and no voluntarily activated motor units. The left peroneus longus muscle showed very similar changes, with very-brief-duration low-amplitude motor unit potentials. Lesser degrees of myopathic change were seen in the left extensor digitorum brevis and lateral gastrocnemius muscles. The left biceps femoris muscle showed no abnormality.

When the patient was 20 years old, EMG of the right tibialis anterior, gastrocnemius, and extensor digitorum brevis muscles revealed no abnormalities.

Muscle Biopsy Findings

When the patient was 11 years old, paraffin-embedded sections of the left tibialis anterior muscle showed extensive myopathic changes with areas of muscle fiber hypertrophy, an increased proportion of fibers with internal nuclei, and many small degenerating and regenerating muscle fibers embedded in connective tissue. A few foci of chronic inflammatory cells were seen without a perivascular distribution.

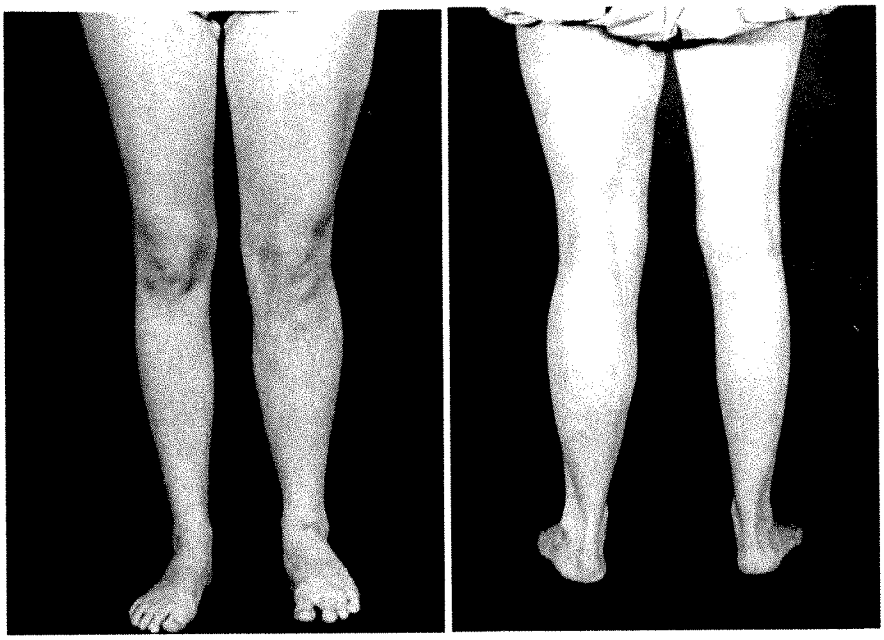

Fig 1.—Front (left) and back (right) views of patient's legs showing the increase in girth of the entire left leg.

When the patient was 15 years old, cryostat sections of the left adductor hallucis muscle showed disseminated necrotic and regenerating fibers, with foci of interstitial inflammatory cells. There were clumps of regenerating fibers and minor changes suggesting fiber-type grouping. There was a considerable increase of interstitial connective tissue, fiber splitting, and fiber hypertrophy (Fig 2).

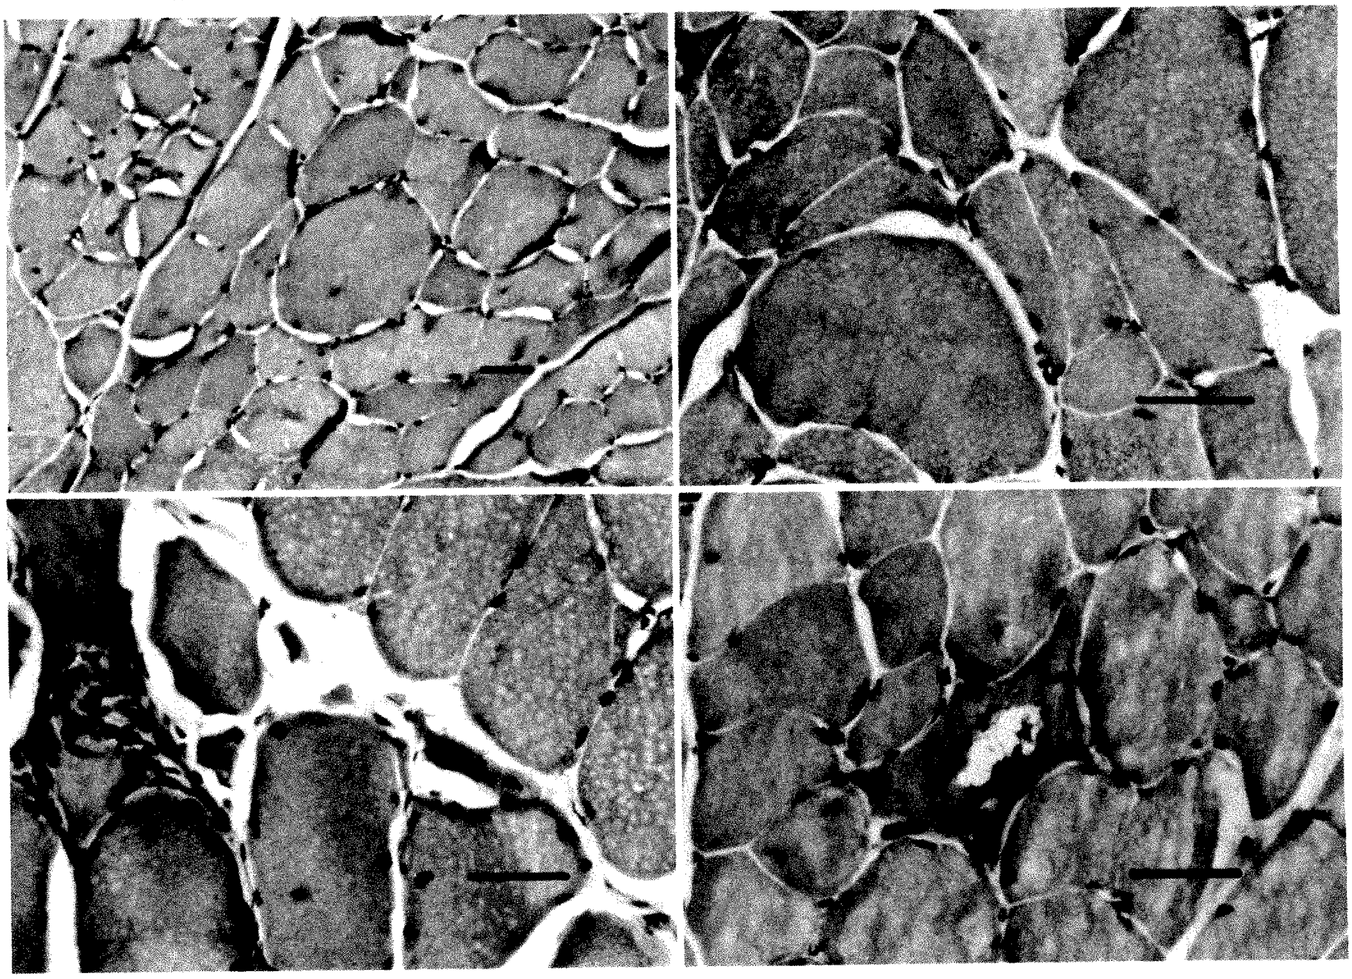
Magnetic Resonance Imaging

When the patient was 18 years old, magnetic resonance imaging showed considerable hypertrophy of the muscles of the left leg including the glutei (Fig 3). The left tibialis anterior muscle, the peroneal muscles, and the deep part of the medial gastrocnemius muscles were atrophic, with areas of abnormal increased signal intensity.

COMMENT

A diagnosis of the rare condition of monomelic hypertrophy requires en-

Fig 2.—Cryostat sections of left adductor hallucis muscle at age 15 years. There is considerable variation in fiber size and shape, with both rounded and angular atrophic fibers (top left) occasional hypertrophic fibers (top right), necrotic fibers (bottom left), and rimmed vacuoles (bottom right) (hematoxylin-eosin; bars = 50 μm).



largement in both bulk and length of all the elements (bones, muscles, and connective tissue) in one limb. There are many causes of this syndrome. Monomelic hypertrophy is most frequently idiopathic, although it can be secondary to local causes such as a proximal arteriovenous malformation of the limb,[18] angiomatosis,[19] or nerve trauma.[20] It has also been associated with neurofibromatosis[9] and Wilms' tumor.[14] A contralateral hemiatrophy, resulting from congenital cerebral lesions such as a porencephalic cyst, must not be misinterpreted as hemihypertrophy of the normal side.

To our knowledge, monomelic hypertrophy and a progressive monomelic myopathy have been associated only in our case and that of Celesia et al.[7] Celesia and colleagues described a woman with right lower-extremity monomelic hypertrophy present from birth, who at the age of 12 years developed progressive footdrop and weakness of the right hip flexors. In both cases, electrophysiologic and pathological studies revealed a typical myopathy. The patient of Celesia and colleagues had spontaneous and percussion myotonia restricted to the affected quadriceps femoris muscle and "bursts of high-frequency discharges to electrode movement and after volitional contraction, characteristic of myotonia," on EMG. Myotonia was absent in our case, although there was considerable membrane irritability with CRDs.

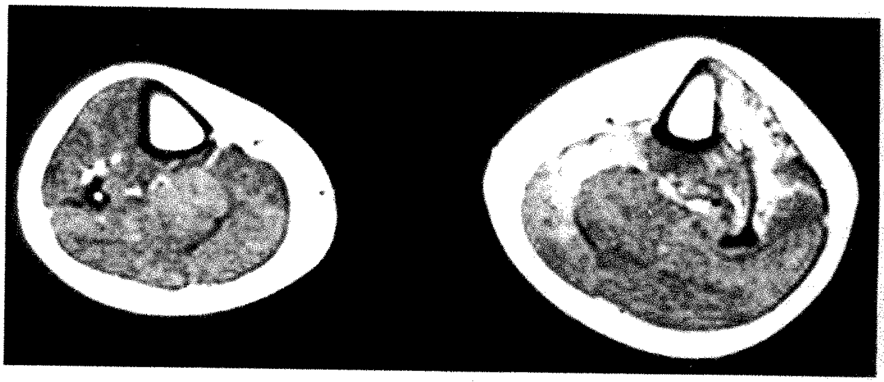


Fig 3.—Magnetic resonance imaging (repetition time, 300 milliseconds; echo time, 30 milliseconds). Coronal view of the legs at midcalf level showing the increase in bulk of most of the muscles on the left, and patchy increased signal in the atrophic tibialis anterior muscle, the peroneal muscles, and the deep part of the medial gastrocnemius muscles.

True myotonic discharges are characterized as repetitive discharges at rates of 20 to 80 Hz of either biphasic spike potentials of less than 5-millisecond duration or positive waves of 5- to 20-millisecond duration, recorded with an EMG needle after voluntary muscle contraction or muscle percussion.[21] They are due to independent, repetitive discharges of single muscle fibers. To be accepted as true myotonic discharges, the amplitude and frequency of the potentials must wax and wane, producing a characteristic divebomber or motorcycle sound in the audio display of the EMG. Complex repetitive discharges are a series of polyphasic or serrated action potentials that may begin spontaneously or after a needle movement; have uniform frequency, shape, and amplitude; and are abrupt in onset, cessation, or change in configuration.[21] The amplitude of CRDs ranges from 100 μV to 1 mV, and the frequency of discharge ranges from 5 to 100 Hz. Complex repetitive discharges are seen in a wide variety of myopathic and lower motor neuron disorders.[22-24] The description of the EMG bursts of activity described in the patient of Celesia et al[7] lacks mention of waxing and waning amplitude and frequency, and their article was published before the criteria for separating true myotonic discharges from CRDs were well established. We believe that the burst of activity in the case of Celesia and colleagues may have been CRDs. The evidence both in our case and in that of Celesia and colleagues indicates that the myopathy was restricted to the hypertrophic limb, although longer follow-up is needed to exclude a very asymmetric presentation of a more generalized myopathy.

Why a progressive myopathy should develop in a limb afflicted with monomelic hypertrophy is unclear. It is possible that at an early embryonic stage the cell(s) destined to give rise to the affected limb segregated a genetic abnormality, such as a chromosomal anomaly or a mutation, that was later responsible both for focal macrosomia and for an abnormality of skeletal muscle. There are as many possible causes for this myopathy as there are inherited disorders of muscle associated with hypertrophy, including Duchenne-type and Becker's muscular dystrophies (although both patients are female), myotonia congenita of Thomsen and of Becker,[25-30] and limb-girdle muscular dystrophy.[31]

Muscle hypertrophy has been reported rarely in association with lesions of nerve, including radicular lesions,[4-6] and with chronic spinal muscular atrophy.[32] Monomelic amyotrophy due to focal anterior horn cell degeneration is now a well-recognized condition,[33] but this has not been reported to be associated with muscle hypertrophy. The increased fiber density in the affected tibialis anterior muscle on single-fiber EMG in our case, together with increased jitter and blocking, suggested some neuronal involvement,[17] although the muscle biopsy findings and EMG indicated that the process was primarily a myopathy.

The various acquired forms of generalized muscle hypertrophy also need to be considered as causes for this monomelic myopathy. Such conditions include de Lange's syndrome,[34] hypothyroid myopathy,[35,36] and amyloid myopathy.[37,38] Hypertrophia musculorum vera is not a specific disease entity but rather is a syndrome of diffuse muscular hypertrophy of multiple causation.[1] Focal nodular myositis[39] may cause focal muscle hypertrophy, and monomelic myositis has been described.[40-42] However, all of these acquired causes of muscle hypertrophy appear unlikely to be relevant in these two cases of congenital monomelic hypertrophy with myopathy in view of the macrosomia and the muscle biopsy changes. It appears, therefore, that the case of Celesia et al[7] and our case represent similar but slightly different diseases of muscle occurring in a limb affected by congenital monomelic hypertrophy. The understanding of the basis of these muscle degenerations may come from advances in the molecular genetics of muscle disease.

We are grateful to Robert Greenwood, MD, for referring this patient and to the Department of Pathology of Duke University, Durham, NC, for access to slides of the pathologic material in this case.

The Comprehensive Headache Center
at The Germantown Hospital and Medical Center
in cooperation with Temple University School of Medicine, Department of Neurology
Presents

The Sixth Headache Symposium

Update in the Diagnosis and Treatment of Headache, Facial Pain and Neuralgia

Presented by a nationally known panel of headache experts.

■

Saturday, March 16, 1991
8:30 A.M. - 3:15 P.M.
at The Germantown Hospital and Medical Center
One Penn Boulevard, Philadelphia, PA
(adjacent to LaSalle University at the intersection of Wister, Chew and Olney Avenues)

Featured Speakers and Topics:

Moderator: Elliott A. Schulman, M.D.*
Attending Neurologist,
The Germantown Hospital and Medical Center;
Associate Professor of Neurology,
Temple University Hospital

Pathogenesis and Current Treatment of Migraine

Stephen D. Silberstein, M.D.*
Chief, Neurology Section,
The Germantown Hospital and Medical Center;
Associate Professor of Neurology,
Temple University Hospital

The Emergency Treatment of Headache

John G. Edmeads, M.D.
Professor of Medicine (Neurology),
University of Toronto

Management of the Cranial Neuralgias and Atypical Facial Pain

Donald J. Dalessio, M.D.
Senior Consultant, Division of Neurology, Scripps Clinic
and Research Foundation, LaJolla, California

Neuro-Ophthalmologic Complications of Migraine Diagnosis and Management of Idiopathic Intracranial Hypertension (Pseudotumor Cerebri)

James J. Corbett, M.D.
Professor and Chairman, Department of Neurology,
University of Mississippi Medical Center

COMPREHENSIVE HEADACHE CENTER
at The Germantown Hospital
and Medical Center

Additional participants will include:

Gregory J. Tramuta, M.D.*, Chief, Psychiatry Section,
The Germantown Hospital and Medical Center;
Associate Clinical Professor of Psychiatry,
Temple University Hospital

Ronald S. Kaiser, Ph.D.*, Licensed Psychologist;
Affiliate, Psychiatry Section,
The Germantown Hospital and Medical Center;
Assistant Professor, Department of Psychiatry,
Temple University

Joseph P. Primavera, III, M.A.*, Licensed
Psychologist; Affiliate, Psychiatry Section,
The Germantown Hospital and Medical Center

William B. Young, M.D., Attending Neurologist,
The Germantown Hospital and Medical Center

A round-table discussion will include controversial topics in headache management and difficult cases. Plan to bring your difficult cases for discussion.

*Co-Director, Comprehensive Headache Center

Funding for this Symposium provided by GLAXO, INC.

Credits:
5 Category I credits for AMA Physician's Recognition Award

Registration Fee:
$25.00 (includes coffee break, lunch and registration materials) Return by March 1, 1991.

Please make checks payable to:
The Germantown Hospital and Medical Center
Comprehensive Headache Center
One Penn Boulevard, Philadelphia, PA 19144

Classified Advertising

All classified advertising orders, correspondence and payments should be directed to: Archives of Neurology, P.O. Box 1510, Clearwater, Florida 34617. Our telephone numbers are: 800-237-9851; 813-443-7666. Please do not send classified ads, payments or related correspondence to the AMA headquarters in Chicago. This causes needless delay.

Inquiries about "BOX NUMBER" advertisements: All replies must be in writing and must cite the box number in the ad. Example: Box ______, c/o AON, P.O. Box 1510, Clearwater, Florida 34617. We are not permitted to divulge the identity of advertisers who wish their mail sent in care of Archives of Neurology.

CLASSIFIED INFORMATION

Regular Classified	1 Time	3 Times or more*
Cost per word	$1.00	$ .90 per issue
Minimum ad: 20 words.		

**In order to earn the three-time rate, your ad must be placed and prepaid at the same time for three or more issues.*

Counting Words: Two initials are considered one word, each abbreviation is considered one word, and figures consisting of a dollar sign and five numerals or less are considered one word. Cities and states consisting of two words or more are counted as one word: i.e., "New York" and "Salt Lake City." Zip code is considered one word and must appear in all ads. Telephone number with area code is considered one word. When box numbers are used for replies, the words "Box ______, c/o AON" are to be counted as three words.

Classified Display	1 Time	3 Times
Full page	$536	$482
Two-thirds page	458	412
One-half page	405	364
One-third page	321	289
One-sixth page	214	193
Column inch	55	50

Minimum display ad: one column inch.
12-time and 24-time rates available on request.

Display Production Charge: The publication will pub-set advertisements upon request. The typesetting fee is 10% of the one-time ad cost shown above. Special requests will be billed to the advertiser and/or agency at the then prevailing rates.

Box Service

Available for all ads. The cost is $15.00 for the first issue only. Responses to your ad will be consolidated in our office and promptly mailed directly to you.

Closing Date

The 25th of the second month prior to issue date. Example: The November issue closes September 25th. No ads can be cancelled after the closing date.

Send all copy, correspondence, production materials and payments to:

Professional Opportunities

EXPANDING DYNAMIC neurology practice — BC/BE neurologist to join a busy, rapidly growing group neurology practice in Virginia suburbs of Washington, DC. Excellent opportunity for a compassionate, personable, hard working person to join our comprehensive neurodiagnostic team. Subspecialty training, especially EEG, evoked potentials, EMG, or sleep disorders preferred. Teaching and faculty appointments available. Send CV to: D. Hope, Neurology Center of Fairfax, Ltd., 3020 Hamaker Court, Fairfax, VA 22031.

Regional medical center for 85,000 population needs neurologist; located in beautiful mountainous eastern Kentucky with state parks and lakes within thirty miles. Progressive community with excellent accredited school system. Active staff; sixty practicing physicians. If interested, send CV to: Dr. John Tummons, Administrator.

Methodist Hospital of Kentucky
911 South Bypass, Pikeville, KY 41501

NEUROLOGIST: Excellent opportunity for board-certified/board-eligible neurologists to join two existing neurologists in a stimulating, busy practice. Marquette General Hospital is a 321-bed regional referral center, with a comprehensive neurophysiology department and state-of-the-art technology that includes magnetic resonance imaging and CT scanning, and a hospital-based family practice residency. Medical students from Michigan State University's College of Human Medicine are regularly assigned to the hospital and offer an opportunity for teaching. Marquette General Hospital and its medical staff are committed to building a center of excellence in the neurosciences and have the necessary financial resources. The development of these services will require the leadership and cooperation of physicians in the field of neurology, neurosurgery, psychiatry, physical medicine and rehabilitation. Salaried and private practice positions are available. If this special opportunity is of interest to you, please send CV to: Robert J. Raica, Marquette General Hospital, 420 West Magnetic Street, Marquette, MI 49855.

BE/BC NEUROLOGIST

To join an associate neurlogy practice in south-central Nebraska. This opportunity comes with the full support of your colleages and offers exceptional life style and practice potential. Income guarantee, relocation, MP, office paid. Send CV or contact: Armando L. Frezza, President, Medical Support Services, 8806 Balcones Club Drive, Austin, TX 78750. Office (800) 288-7420; FAX (512) 331-6741.

NEUROLOGIST to join dynamic, midwest neurology group. This very busy practice is seeking an energetic neurologist with a strong interest in the clinical care of patients. This opportunity is located in a desirable, midwestern community abundant in cultural and sporting activities. The practice has a well-equipped radiology department with MRI and CT, and also, neurophysiology and neuropsychology departments. The appropriate candidate must be energetic, pleasant, BC/BE, with EMG experience. Please send curriculum vitae to: Box #814, c/o AON.

ATTENTION PHYSICIAN RECRUITERS. The "Classified Advertising" sections now in all nine AMA Specialty Journals target the physician you want. These highly visible sections put your message in the hands of every specialist that qualifies for your professional opportunity, every month. To place the ad of your choice, any size, call toll free: (800) 237-9851; or in Florida (800) 553-8288.

Professional Opportunities

BC/BE NEUROLOGIST NEEDED — California. Excellent opportunity to establish your own private practice with no investment, guaranteed income. Strong referral base. Proficiency in EEG/EMG required. Well equipped, 112-bed, full-service hospital. Our service area population is now 90,000; a growing area with new businesses and stable economy. Located in central California near Sequoia National Park, Tulare offers an excellent family-oriented lifestyle and all expected amenities. Beautiful homes close to hospital and office are affordably priced. Good schools, many community activities and abundant recreation including golf, tennis, mountain and equestrian activities. Easy access to all California's major metropolitan and resort areas. Please contact: Tulare District Hospital Physician Recruiting Office, P.O. Box 90112, Los Angeles, CA 90009. (800) 468-2687.

CHARLOTTE, NORTH CAROLINA: High quality group of six neurologists, all of whom are subspecialized, seeks to add a well-trained neuroncologist. Contact: Mike Kaufman, MD, 126 Cottage Place, Charlotte, NC 28207; or call: (704) 334-7311.

MAUI ORTHOPEDIC and Sports Medicine seeks neurologist to establish independent practice. Contact: William Gfeller, 450 Hookahi Street, Wailuku, Maui, HI 96793. (808) 244-5541.

— SOUTH FLORIDA —

Suite 1850
St. Louis, MO 63117

Fellowships

PAIN FELLOWSHIP. The Pain Service in the Department of Neurology at Memorial Sloan-Kettering Cancer Center is seeking a board-eligible/board-certified neurologist for a pain fellowship. This is a one- or two-year position that offers comprehensive training in pain evaluation and treatment, with a strong emphasis on cancer pain. Fellows will participate in clinical investigations of neuro-oncologic pain syndromes and the pharmacology of opioid analgesics. Laboratory research opportunities directed at the mechanisms of opiate action and the molecular pharmacology of opiate receptors are also available. Please contact: K.M. Foley, Department of Neurology, Memorial Sloan-Kettering Cancer Center, 1275 York Avenue, New York, NY 10021.

FELLOWSHIP in Cerebrovascular Disease: Fellowships in cerebrovascular disease are available in the Department of Neurology at the University of Iowa. Comprehensive clinical training in management of patients with stroke is complemented by opportunities for clinical or basic research. Fellows are active participants in patient care and collaborate in several on-going local and multi-center clinical research studies. Candidates should be board-eligible or -certified in neurology and be licensed to practice medicine in the United States. Please send inquiries to either Harold P. Adams, Jr., MD, or Jose Biller, MD, Division of Cerebrovascular Diseases, Department of Neurology, University of Iowa, Iowa City, IA 52242. Or call: (319) 356-4110. The University of Iowa is an affirmative action/equal opportunity employer. Women, minorities and handicapped are encouraged to apply.

Neuro-Ophthalmology Fellowship

The Departments of Ophthalmology and Neurology, University of Michigan. Position for one year period, July 7, 1992 to July 6, 1993. Trainee appointed as a lecturer with stipend and fringe benefits. Inquiries (before June 1, 1991) to: Jonathan D. Trobe, MD,

W K Kellogg Eye Center
1000 Wall Street, Ann Arbor, MI 48105
The University of Michigan
is an affirmative action employer.

GERIATRIC NEUROLOGY FELLOWSHIP. A two-year fellowship is available in geriatric neurology, beginning July 1, 1991. This VA-supported fellowship provides multi-disciplinary training in geriatric neurology with formal rotations on the 17-bed Geriatric Evaluation and Management Service at the Portland VA Medical Center. Fellows will also participate in clinical and research activities of the Alzheimer's Disease Center of Oregon and the Oregon Brain Aging Study at both the VA Medical Center and Oregon Health Sciences University. Emphasis will be placed on the design and implementation of independent research protocols. A broad range of research opportunities are available and include such topics a quantitative image analysis, the neuropharmacology of movement disorders, cerebrovascular disease in the elderly, and the neurology, neuropsychology and neuropathology of the very old. Applicants must be board-eligible or -certified in neurology. To apply, send CV and two letters of recommendation to: Jeffrey Kaye, MD, Director, Geriatric Neurology, Portland VA Medical Center, 3710 SW U.S. Veterans Hospital Road, P.O. Box 1034, Portland, OR 97207. Telephone: (503) 273-5171 or (503) 494-7772. The Department of Veterans Affairs and the Oregon Health Sciences University are equal opportunity employers.

THE DEPARTMENT OF NEUROLOGY, University of Louisville has an opening for Clinical Neurophysiology Fellowship for 1991-92. Candidate will have the options to combine EEG with EMG or evoked potentials or clinical polysomnography. Interested applicants should forward their curriculum vitae to: Vasudeva Iyer, MD, Department of Neurology, University of Louisville, Louisville, KY 40292. (502) 588-7981.

PLEASE NOTE—Address replies to box number ads as follows: Box number, ______, c/o AON, P.O. Box 1510, Clearwater, FL 34617.

Neuro-oncology Fellowships/ Instructorships July 1991 and 1992

The U.C., San Francisco Neuro-oncology Service offers unprecedented opportunities to participate in chemotherapy and radiation therapy trials of children and adults with brain tumors.

Practice is primarily outpatient; some 2,000 patient visits per year are seen. An optional second year of laboratory research is available.

Applicants for this position must possess a California medical license and be board-eligible or board-certified in neurology, neurosurgery, or medical oncology. There are two positions offered each year.

Michael Prados, MD
Department of Neurological Surgery
Neuro-oncology Service, ACC841
UNIVERSITY OF CALIFORNIA SAN FRANCISCO
San Francisco, CA 94143-0372

The University of California is an equal opportunity/affirmative action employer. Women and minorities are encouraged to apply.

POSTDOCTORAL FELLOWSHIP IN NEUROBEHAVIOURAL RESEARCH

The Rotman Research Institute of Baycrest Centre for Geriatric Care in Toronto is offering a two-year Postdoctoral Fellowship, starting in the summer of 1991.

The Rotman Research Institute is dedicated to research into neurobehavioural changes which occur during aging, with a specific focus on memory and frontal lobe functions. Baycrest Centre for Geriatric Care is fully affiliated with the University of Toronto and provides a comprehensive range of inpatient and outpatient services to the elderly in behavioural neurology, geriatric medicine, psychiatry, psychology, speech pathology, and other therapeutic services.

A minimum of eighty percent of the positions will be devoted to research and related activities. The stipend is equivalent to the fellowship scales of the Medical Research Council of Canada, and includes an allowance for travel and other research expenses. The position is open to applicants with a PhD, MD, or equivalent degree. In accordance with Employment & Immigration Canada regulations, preference will be given to Canadian citizens and permanent residents of Canada.

Applicants should send a complete CV and arrange to have three letters of reference sent separately, by February 1, 1991, to:

DR. DONALD T. STUSS
DIRECTOR OF RESEARCH
ROTMAN RESEARCH INSTITUTE
BAYCREST CENTRE
FOR GERIATRIC CARE
3560 BATHURST STREET

Fellowships

NEUROLOGICAL REHABILITATION Fellowship: The Department of Neurology of the University of California at Los Angeles offers an ongoing one- and two-year fellowship for BE/BC neurologists in neurorehabilitation starting every July. Acute inpatient and outpatient training within the U.C.L.A. Comprehensive Rehabilitation Program also provides opportunities in basic and clinical research in mechanisms of cognitive and motor recovery. The Functional Assessment Lab offers biochemical studies of gait, balance and strength. The inpatient rehab unit at Daniel Freeman Memorial Hospital provides additional training. Send inquiries, CV. and letters of recommendation to: Bruce H. Dobkin, MD, Professor of Neurology, UCLA School of Medicine, 300 UCLA Medical Plaza, Suite B200, Los Angeles, CA 90024-6975.

Faculty Positions

THE DEPARTMENT OF NEUROLOGY at the University of Louisville, School of Medicine is seeking a faculty member for a full-time academic appointment. Applicant must be board-eligible in neurology and neurodiagnostics, preferably with a completed fellowship in neurophysiology and electrodiagnostic medicine. Must be committed to education both at the undergraduate and graduate levels. Contact: William H. Olson, MD, Chairman, Department of Neurology, University of Louisville, Louisville, KY 40292. (502) 588-7981. EO/AAE.

THE DEPARTMENT OF NEUROLOGY at the University of Missouri-Columbia School of Medicine is recruiting two pediatric neurologists. These faculty members will be responsible for teaching, patient care, and service with academic rank and compensation based upon training and experience. Candidates should have a strong clinical interest in pediatric neurology. Interested candidates should be board-certified or eligible for board-certification by the American Board of Psychiatry and Neurology. Please contact: William J. Crowley, Jr., MD, Professor and Chairman, UMC School of Medicine, Department of Neurology, M741 Health Sciences Center, Columbia, MO 65212. The University of Missouri-Columbia is an equal opportunity and affirmative action institution.

THE UNIVERSITY OF MISSISIPPI Medical Center Department of Neurology invites applications for position of assistant professor from board-certified individuals with strong research, clinical and teaching skills. Persons with expertise in neuro-oncology, vascular disease and epilepsy are especially being sought. Please submit a letter of intent, curriculum vitae, and the names of three referring physicians to: Dr. James J. Corbett, Chairman, Department of Neurology, The University of Mississippi Medical Center, Jackson, MS 39216-4505. The University of Mississippi is an equal opportunity employer, M/F/H/V.

ACADEMIC NEUROLOGIST with board-eligibility in EMG sought by the Department of Neurology at The George Washington University Medical Center in Washington, DC. This non-tenure track, junior faculty position includes teaching responsibilities, patient care and the opportunity to develop a neuromuscular/EMG program. A competitive salary and excellent fringe benefits are provided. The George Washington University is an equal opportunity employer. Applications will be accepted until the position is filled. Please send inquiries and curriculum vitae to: Helene A. Emsellem, MD, Acting Chairman, Department of Neurology, 2150 Pennsylvania Avenue, NW, Suite 7-407, Washington, DC 20037.

ACADEMIC NEUROLOGIST with board-eligibility in clinical neurophysiology is sought by The Department of Neurology of The George Washington University Medical Center in Washington, DC. This tenure track position offers an opportunity to be involved in an active academic EEG/Sleep Laboratory and includes teaching and patient care activities. A competitive salary and excellent fringe benefits are provided. The George Washington University is an equal opportunity employer. Applications will be accepted until the position is filled. Please send inquiries and curriculum vitae to: Helene A. Emsellem, MD, Acting Chairman, Department of Neurology, 2150 Pennsylvania Avenue, NW, Suite 7-407, Washington, DC 20037.

Faculty Positions

FULL-TIME ACADEMIC POSITION in small, but ambitious department of neurology in private medical school in southeastern Virginia. Candidate should be BC/BE in neurology and have special expertise and additional training in clinical neuromuscular disease and electrodiagnostic medicine suitable for certification by ABEM. Training in muscle biopsy/pathology is especially desirable. Contact: Thomas R. Pellegrino, MD, Professor and Chairman, Department of Neurology, 825 Fairfax Avenue, Norfolk, VA 23507. (804) 446-5940.

LOYOLA UNIVERSITY Chicago Stritch School of Medicine, Department of Neurology invites applications for two positions at the assistant professor level. Applicants should be board-eligible or -certified in neurology and have subspecialty expertise in either epilepsy, movement disorders, cerebrovascular or neuromuscular diseases. Preference will be given to candidates with clinical research interests. Send CV to: Gastone Celesia, MD, Chairman, Neurology Department, Loyola University Chicago, 2160 South First Avenue, Chicago, IL 60153. Loyola University Chicago is an equal opportunity/affirmative action employer.

FULL-TIME ACADEMIC POSITION available in small but ambitious department of neurology in private medical school in southeastern Virginia; should be BC/BE clinical neurologist with special expertise and fellowship training in clinical neurophysiology suitable for certification by ABCN. Interest and expertise in clinical research highly desirable. Available facilities include intraoperative EEG/EP, ambulatory cassette EEG, video EEG, EEG/EP mapping. Contact: Thomas R. Pellegrino, Professor and Chairman, Department of Neurology, Eastern Virginia Medical School, 825 Fairfax Avenue, Norfolk, VA 23507. (804) 446-5940.

Residencies

THE UNIVERSITY OF CHICAGO Neurology Department is offering a second year neurology residency position (PGY 3) beginning July 1991. For information contact: Richard P. Kraig, PhD, MD, Residency Director, Department of Neurology, University of Chicago Medical Center, 5841 South Maryland, BH - Box 425, Chicago, IL 60637. (312) 702-0151.

Practices Available

JULY 1991—PRACTICE. Outstanding opportunity. $200K net probable by end of first year. Fully equipped neurologic institute. Only the best need apply. Send CV at once: Southeastern Neuroscience Institute, Inc., 5143 University Boulevard, West, Suite 3, Jacksonville, FL 32216-5939. (904) 733-0707; FAX (904) 730-9173.

Practices Available

NEUROLOGY PRACTICES for sale—Two established neurology practices for sale in Los Angeles County. A highly profitable, general neurology practice established over ten years, located on the campus of a major medical center in Burbank, California; and a busy pediatric neurology practice in Hollywood, California affiliated with major teaching and community hospitals. Call: Alex Guttman, Principal, Arthur S. Shorr and Associates, Inc., Consultants to Health Care Providers: (818) 348-6632.

Positions Available

ADULT NEUROLOGIST, BC/BE to join a well established, growing, solo practice with outside neurological coverage in the Akron, Ohio area. Teaching, laboratory and clinical practice activities. The very latest of facilities available at teaching hospitals. Partnership anticipated. Salary and benefits competitive. A good sense of humor required. This is a wonderful opportunity for the right person. Please send CV to: Box #811, c/o AON.

Medical Equipment/Supplies

1985 NIHON KOHDEN Neuropack 8 Evoked Potential Machine-VEP, BAEP, SSEP; with color monitor and plotter. Excellent condition: $15,000. (703) 885-6000.

Medical Services

MRI/CT INTERPRETATIONS by board-certified radiologists via teleradiology or overnight mail. Teleradiology Associates, P.A., One University Place, Suite 350, Durham, NC 27707. (919) 419-1000.

Computers/Software

PRACTICE MANAGEMENT, insurance billing, medical records, and electronic claims systems. American Medical Software (800) 423-8836.

Miscellaneous

SECOND DARTMOUTH International Conference on Epilepsy and The Corpus Callosum, Hanover, New Hampshire, August 13-17, 1991. Contact: Professor Alexander G. Reeves, Section of Neurology, Dartmouth-Hitchcock Medical Center, Hanover, NH 03756. FAX: (603) 646-8756. Telephone: (603) 646-7916.

PLEASE NOTE—Address replies to box number ads as follows: Box number, ________, c/o AON, P.O. Box 1510, Clearwater, FL 34617.

Neurology Boards Review Course

January 6-11 – Los Angeles March 17-22 – Houston
April 11-13 – New Orleans October 24-26 – Philadelphia

Now, your course for written and oral boards offers unlimited mock exams

OBJECTIVES:
- Increase basicscience knowledge and clinical skills in neurology
- Assist neurology residents to study efficiently
- Prepare board candidates to take board examinations
- Provide practicing neurologists with a review and update

METHODS:
- HOME STUDY MATERIALS with questions and answers based on previous examinations
- SEMINAR with projection slides and syllabus
- PRACTICE EXAMS with oral and written parts

Part I Courses:
January 6-11 – Los Angeles
March 17-21,'92 – Houston

Basic Sciences
Neuroanatomy
Neuropathology
Neurochemistry
Neurophysiology
Neuropharmacology
Neuroimmunology
Neurogenetics

Clinical Sciences
Neuroimaging
Neuro-otology
Neuro-ophthalmology
Neuroendocrinology
Psychiatry
Alcohol & Substance Abuse
Neuropharmacology

Sensation and Behavior
Headache and Pain
Higher Cortical Function
Movement Disorders
Seizures and Epilepsy
Delirium and Confusion
Stupor and Coma
Dementia and Alzheimer's

Neurologic Diseases
Infectious Diseases
Stroke & C.S.F. Disorders
Tumors and Trauma
Spinal Cord and Disc
Demyelinative Diseases
Multiple Sclerosis
Metabolic & Toxic Diseases
Parkinson's Dieases
Developmental Disorders
Sleep Disorders

Neuromuscular & Child
Neuropathies
Myopathies
Neuromuscular Junction
Neonatal Neurology
Pediatric Neurology

Optional Day
January 12 – Los Angeles
March 16 – Houston

Skull Base Surgery
Cerebropontine Angle
Craniovascular Surgery
Pituitary Surgery
Spinal Surgery
Neuroanesthesiology
Surgical Critical Care

Part II Courses:
April 11-13 – New Orleans
October 24-26 – Philadelphia

The Part II Course is designed to prepare board candidates for their oral exam. January and March courses are for both written and oral exams – with lectures and mock oral daily.

The three day course will be only mock oral exams on differential diagnosis, treatment options, and complications. Following each exam faculty will give a critique.

Each participant will have an exam and critique session and observation of other sessions. Additional 25 minute sessions may be arranged for $70 and private sessions may be had for an extra $30.

*"Accommodations were comfortable..."**

COURSE AND LOCATION:
The Part I Course consists of lectures and evening mock oral exams to help you prepare for your written and oral exams. The Part II Course is all mock oral exams for three days before and in the same city as each oral exam. Home study materials will be sent before the course. Past participants recommend taking the course well before written and oral exams and repeating for half price immediately before your exam. The course hotel will be the best available combination of bargain rates and excellent study environment.

*"...and those little extras..."**

LOWEST AIR FARES:
For our special group discount fares, please call Reliable Travel toll-free 1-800-548-8185.

*"...the most education for the money."**

FEES AND COURSE HOURS:

	Phy.	Res.	Hrs.
• Physicians or Residents			
• Part I Course (6 days):	$750	$500	60
repeating within 2 yrs.:	$375	$375	60
• Optional Day	$150	$100	8
• Part II Course (3 days)	$540	$360	28
repeating within 2 yrs.:	$270	$270	28
• Extra mock oral exams:	$ 70	$ 70	1/2
• Private mock oral exams:	$100	$100	1/2

- **Add 10% within 10 days of the course.**
- Attendees not in course hotel add $20/day.
- A deposit of $50 will reserve your position.
- Home study materials will be mailed after half of the registration fee is received.

*"...home study material was extremely helpful..."**

REFUNDS:
- Subject to a $50 fee, refunds will be made up until the seminar begins.
- Cancellation after mailing home study material requires retention of half of the fee.

*"I feel [the course] helped me pass..."**

Dilantin® Kapseals®
(extended phenytoin sodium capsules, USP)

Dilantin® KAPSEALS® (Extended Phenytoin Sodium Capsules, USP)

Before prescribing, please see full prescribing information. A Brief Summary follows.

INDICATIONS AND USAGE: Dilantin is indicated for the control of generalized tonic-clonic (grand mal) and complex partial (psychomotor, temporal lobe) seizures and prevention and treatment of seizures occurring during or following neurosurgery.

Phenytoin serum level determinations may be necessary for optimal dosage adjustments (see Dosage and Administration and Clinical Pharmacology).

CONTRAINDICATIONS: Phenytoin is contraindicated in those patients who are hypersensitive to phenytoin or other hydantoins.

WARNINGS: Abrupt withdrawal of phenytoin in epileptic patients may precipitate status epilepticus. When, in the judgment of the clinician, the need for dosage reduction, discontinuation, or substitution of alternative antiepileptic medication arises, this should be done gradually. However, in the event of an allergic or hypersensitivity reaction, rapid substitution of alternative therapy may be necessary. In this case, alternative therapy should be an antiepileptic drug not belonging to the hydantoin chemical class.

There have been a number of reports suggesting a relationship between phenytoin and the development of lymphadenopathy (local or generalized) including benign lymph node hyperplasia, pseudolymphoma, lymphoma, and Hodgkin's Disease. Although a cause and effect relationship has not been established, the occurrence of lymphadenopathy indicates the need to differentiate such a condition from other types of lymph node pathology. Lymph node involvement may occur with or without symptoms and signs resembling serum sickness, eg, fever, rash and liver involvement.

In all cases of lymphadenopathy, follow-up observation for an extended period is indicated and every effort should be made to achieve seizure control using alternative antiepileptic drugs.

Acute alcoholic intake may increase phenytoin serum levels while chronic alcoholic use may decrease serum levels.

In view of isolated reports associating phenytoin with exacerbation of porphyria, caution should be exercised in using this medication in patients suffering from this disease.

Usage in Pregnancy: A number of reports suggests an association between the use of antiepileptic drugs by women with epilepsy and a higher incidence of birth defects in children born to these women. Data are more extensive with respect to phenytoin and phenobarbital, but these are also the most commonly prescribed antiepileptic drugs; less systematic or anecdotal reports suggest a possible similar association with the use of all known antiepileptic drugs.

The reports suggesting a higher incidence of birth defects in children of drug-treated epileptic women cannot be regarded as adequate to prove a definite cause and effect relationship. There are intrinsic methodological problems in obtaining adequate data on drug teratogenicity in humans; genetic factors or the epileptic condition itself may be more important than drug therapy in leading to birth defects. The great majority of mothers on antiepileptic medication deliver normal infants. It is important to note that antiepileptic drugs should not be discontinued in patients in whom the drug is administered to prevent major seizures, because of the strong possibility of precipitating status epilepticus with attendant hypoxia and threat to life. In individual cases where the severity and frequency of the seizure disorder are such that the removal of medication does not pose a serious threat to the patient, discontinuation of the drug may be considered prior to and during pregnancy, although it cannot be said with any confidence that even minor seizures do not pose some hazard to the developing embryo or fetus. The prescribing physician will wish to weigh these considerations in treating or counseling epileptic women of childbearing potential.

In addition to the reports of increased incidence of congenital malformation, such as cleft lip/palate and heart malformations, in children of women receiving phenytoin and other antiepileptic drugs, there have more recently been reports of a fetal hydantoin syndrome. This consists of prenatal growth deficiency, microcephaly and mental deficiency in children born to mothers who have received phenytoin, barbiturates, alcohol, or trimethadione. However, these features are all interrelated and are frequently associated with intrauterine growth retardation from other causes.

There have been isolated reports of malignancies, including neuroblastoma, in children whose mothers received phenytoin during pregnancy.

An increase in seizure frequency during pregnancy occurs in a high proportion of patients, because of altered phenytoin absorption or metabolism. Periodic measurement of serum phenytoin levels is particularly valuable in the management of a pregnant epileptic patient as a guide to an appropriate adjustment of dosage. However, postpartum restoration of the original dosage will probably be indicated.

Neonatal coagulation defects have been reported within the first 24 hours in babies born to epileptic mothers receiving phenobarbital and/or phenytoin. Vitamin K has been shown to prevent or correct this defect and has been recommended to be given to the mother before delivery and to the neonate after birth.

PRECAUTIONS: General: The liver is the chief site of biotransformation of phenytoin; patients with impaired liver function, elderly patients, or those who are gravely ill may show early signs of toxicity.

A small percentage of individuals who have been treated with phenytoin has been shown to metabolize the drug slowly. Slow metabolism may be due to limited enzyme availability and lack of induction; it appears to be genetically determined.

Phenytoin should be discontinued if a skin rash appears (see "Warnings" section regarding drug discontinuation). If the rash is exfoliative, purpuric, or bullous or if lupus erythematosus, Stevens-Johnson syndrome, or toxic epidermal necrolysis is suspected, use of this drug should not be resumed and alternative therapy should be considered. (See Adverse Reactions.) If the rash is of a milder type (measles-like or scarlatiniform), therapy may be resumed after the rash has completely disappeared. If the rash recurs upon reinstitution of therapy, further phenytoin medication is contraindicated.

Phenytoin and other hydantoins are contraindicated in patients who have experienced phenytoin hypersensitivity. Additionally, caution should be exercised if using structurally similar (eg, barbiturates, succinimides, oxazolidinediones and other related compounds) in these same patients.

Hyperglycemia, resulting from the drug's inhibitory effects on insulin release, has been reported. Phenytoin may also raise the serum glucose level in diabetic patients.

Osteomalacia has been associated with phenytoin therapy and is considered to be due to phenytoin's interference with Vitamin D metabolism.

Phenytoin is not indicated for seizures due to hypoglycemic or other metabolic causes. Appropriate diagnostic procedures should be performed as indicated.

Phenytoin is not effective for absence (petit mal) seizures. If tonic-clonic (grand mal) and absence (petit mal) seizures are present, combined drug therapy is needed.

Serum levels of phenytoin sustained above the optimal range may produce confusional states referred to as "delirium," "psychosis," or "encephalopathy," or rarely irreversible cere
dysfunction. Accordingly, at the first sign of acute toxicity, plasma levels are recommended
reduction of phenytoin therapy is indicated if plasma levels are excessive; if symptoms p
termination is recommended. (See Warnings.)

Information for Patients: Patients taking phenytoin should be advised of the importa
adhering strictly to the prescribed dosage regimen, and of informing the physician of any c
condition in which it is not possible to take the drug orally as prescribed, eg, surgery, et

Patients should also be cautioned on the use of other drugs or alcoholic beverages witho
seeking the physician's advice.

Patients should be instructed to call their physician if skin rash develops.

The importance of good dental hygiene should be stressed in order to minimiz
development of gingival hyperplasia and its complications.

Do not use capsules which are discolored.

Laboratory Tests: Phenytoin serum level determinations may be necessary to achieve o
dosage adjustments.

Drug Interactions: There are many drugs which may increase or decrease phenytoin le
which phenytoin may affect. Serum level determinations for phenytoin are especially h
when possible drug interactions are suspected. The most commonly occurring drug intera
are listed below: 1. Drugs which may increase phenytoin serum levels include: acute al
intake, amiodarone, chloramphenicol, chlordiazepoxide, diazepam, dicumarol, disul
estrogens, H_2-antagonists, halothane, isoniazid, methylphenidate, phenothiaz
phenylbutazone, salicylates, succinimides, sulfonamides, tolbutamide, trazodone.

2. Drugs which may decrease phenytoin levels include: carbamazepine, chronic alcohol a
reserpine, and sucralfate. Moban® brand of molindone hydrochloride contains calciu
which interfere with the absorption of phenytoin. Ingestion times of phenytoin and a
preparations containing calcium should be staggered in patients with low serum phenytoin
to prevent absorption problems.

3. Drugs which may either increase or decrease phenytoin serum levels include: phenoba
sodium valproate, and valproic acid. Similarly, the effect of phenytoin on phenobarbital, va
acid, and sodium valproate serum levels is unpredictable.

4. Although not a true drug interaction, tricyclic antidepressants may precipitate seizu
susceptible patients and phenytoin dosage may need to be adjusted.

5. Drugs whose efficacy is impaired by phe
include: corticosteroids, coumarin anticoagu
digitoxin, doxycycline, estrogens, furosemide,
contraceptives, quinidine, rifampin, theophy
vitamin D.

Drug/Laboratory Test Interactions: Phenytoin
cause decreased serum levels of protein-bound i
(PBI). It may also produce lower than normal valu
dexamethasone or metyrapone tests. Phenytoi
cause increased serum levels of glucose, alkaline
phatase, and gamma glutamyl transpeptidase (
Carcinogenesis: See "Warnings" section for info
tion on carcinogenesis.

Pregnancy: See Warnings.

Nursing Mothers: Infant breast-feeding is not recommended for women taking this drug bec
phenytoin appears to be secreted in low concentrations in human milk.

ADVERSE REACTIONS: Central Nervous System: The most common manifestations encoun
with phenytoin therapy are referable to this system and are usually dose-related. These in
nystagmus, ataxia, slurred speech, decreased coordination and mental confusion. Dizzi
insomnia, transient nervousness, motor twitchings, and headaches have also been observed.
have also been rare reports of phenytoin induced dyskinesias, including chorea, dystonia, tr
and asterixis, similar to those induced by phenothiazine and other neuroleptic drugs.

A predominantly sensory peripheral polyneuropathy has been observed in patients rece
long-term phenytoin therapy.

Gastrointestinal System: Nausea, vomiting, constipation, toxic hepatitis and liver dama
Integumentary System: Dermatological manifestations sometimes accompanied by fever
included scarlatiniform or morbilliform rashes. A morbilliform rash (measles-like) is the
common; other types of dermatitis are seen more rarely. Other more serious forms which
be fatal have included bullous, exfoliative or purpuric dermatitis, lupus erythematosus, Ste
Johnson syndrome, and toxic epidermal necrolysis (see Precautions).
Hemopoietic System: Hemopoietic complications, some fatal, have occasionally been rep
in association with administration of phenytoin. These have included thrombocytopenia, le
penia, granulocytopenia, agranulocytosis, and pancytopenia with or without bone marrow
pression. While macrocytosis and megaloblastic anemia have occurred, these conditions us
respond to folic acid therapy. Lymphadenopathy including benign lymph node hyperplasia, p
dolymphoma, lymphoma, and Hodgkin's Disease have been reported (see Warnings).
Connective Tissue System: Coarsening of the facial features, enlargement of the lips, gin
hyperplasia, hypertrichosis, and Peyronie's Disease.
Cardiovascular: Periarteritis nodosa.
Immunologic: Hypersensitivity syndrome (which may include, but is not limited to, sympt
such as arthralgias, eosinophilia, fever, liver dysfunction, lymphadenopathy or rash), syst
lupus erythematosus, immunoglobulin abnormalities.

OVERDOSAGE: The lethal dose in children is not known. The lethal dose in adults is estim
to be 2 to 5 grams. The initial symptoms are nystagmus, ataxia, and dysarthria. Other sign
tremor, hyperreflexia, lethargy, slurred speech, nausea, vomiting. The patient may bec
comatose and hypotensive. Death is due to respiratory and circulatory depression.

There are marked variations among individuals with respect to phenytoin plasma levels w
toxicity may occur. Nystagmus, on lateral gaze, usually appears at 20 mcg/mL, ataxia a
mcg/mL, dysarthria and lethargy appear when the plasma concentration is over 40 mcg/mL
as high a concentration as 50 mcg/mL has been reported without evidence of toxicity. As m
as 25 times the therapeutic dose has been taken to result in a serum concentration over
mcg/mL with complete recovery.

Treatment: Treatment is nonspecific since there is no known antidote.

The adequacy of the respiratory and circulatory systems should be carefully observed
appropriate supportive measures employed. Hemodialysis can be considered since pheny
is not completely bound to plasma proteins. Total exchange transfusion has been used in
treatment of severe intoxication in children.

In acute overdosage the possibility of other CNS depressants, including alcohol, shoul
borne in mind.

Caution – Federal law prohibits dispensing without prescription. 0362G

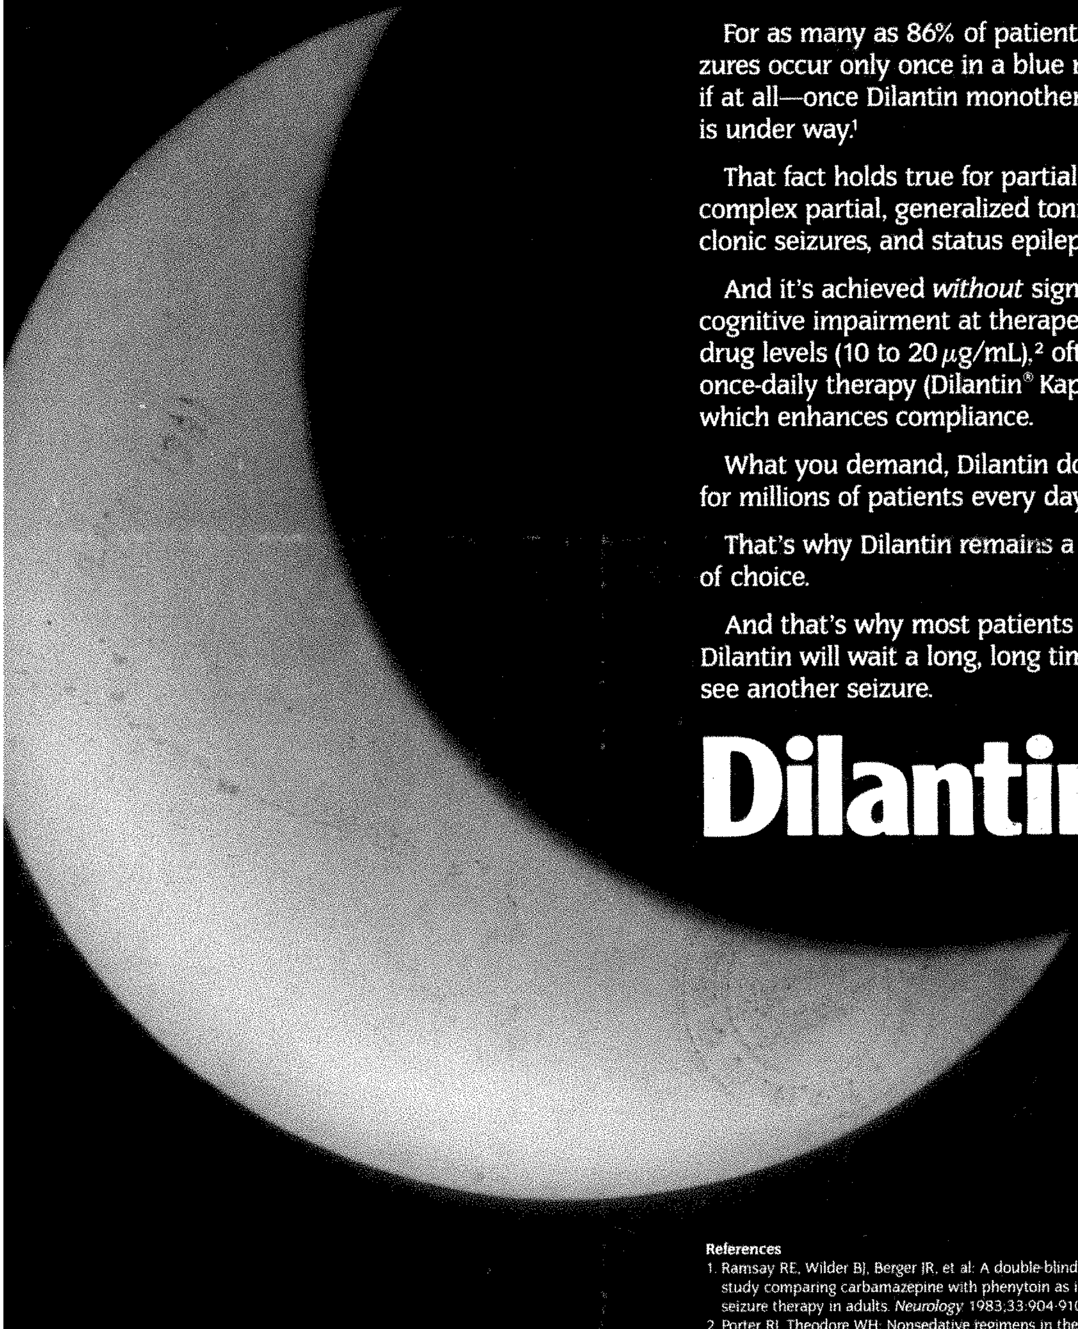
PD-12-JA-4364-P-4A(2-



s rare as a seizure on ilantin® (extended phenytoin sodium capsules, USP) 100 mg

For as many as 86% of patients, seizures occur only once in a blue moon—if at all—once Dilantin monotherapy is under way.[1]

That fact holds true for partial, complex partial, generalized tonic-clonic seizures, and status epilepticus.

And it's achieved *without* significant cognitive impairment at therapeutic drug levels (10 to 20 μg/mL),[2] often *with* once-daily therapy (Dilantin® Kapseals®), which enhances compliance.

What you demand, Dilantin does—for millions of patients every day.

That's why Dilantin remains a drug of choice.

And that's why most patients on Dilantin will wait a long, long time to see another seizure.

Dilantin®

e in a blue moon" describes the phenomenon in which moon appears as a brilliant blue. Seen worldwide following volcanic eruption of Krakatoa in 1883, the blue moon occurs when atmospheric cloud droplets, each less than 5 μm in meter, form in abundance—an exceedingly rare event.[3]

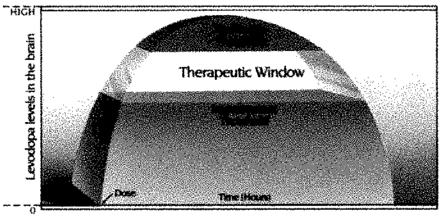
Sinemet®...for many patients with Parkinson's disease, the foundation of therapy for 15 years.

Sinemet®
(Carbidopa-Levodopa)
The Delicate Balance

Only Sinemet® helps you maintain the delicate balance needed for clinical control of Parkinson's disease.



Balancing Dopamine Replacement and Patient Response *Managing the symptoms of Parkinson's disease can be an ongoing balancing act, particularly as the disease progresses and the therapeutic window changes. By adjusting Sinemet® dosage strength and frequency according to patient needs, physicians can achieve the delicate balance needed between dopamine replacement and therapeutic response.*

The management of levodopa therapy in Parkinson's disease can be complex. It calls for a delicate balance between the relief of symptoms by the replacement of dopamine in the brain and the occurrence of side effects.

Dopamine replacement is the mainstay of therapy in Parkinson's disease. Only Sinemet® re-establishes dopamine levels in the brain.

But, too much or too little dopamine can affect the patient's quality of life. So dosage must be monitored and adjusted as the disease progresses, because the therapeuti window narrows over time.

Sinemet® provides you the flexibility needed to adjust dosage based on the individual patient's therapeutic window...by changing dosing frequency...dosage strength... or by changing the ratio between carbidopa and levodopa.

Nothing else helps you maintain the delicate balance needed to manage the signs and symptoms of Parkinson's disease like Sinemet®.

Because carbidopa permits more levodopa to reach the brain and, thus, more dopamine to be formed, dyskinesias may occur at lower doses and sooner with Sinemet® than with levodopa. The occurrence of dyskinesias may require dosage reduction. Please see a brief summary of prescribing information on the adjoining page.

Sinemet®
(Carbidopa-Levodopa)

For many patients with Parkinson's disease

Dosage Guidelines

***Individualized dosage—a key to clinical success with Sinemet*®**

- Begin when symptoms first interfere with normal function
- Adjust as necessary to help maintain relief of symptoms

1

For initial therapy...Start with:

SINEMET 25-100

containing 25 mg carbidopa (anhydrous equivalent) and 100 mg levodopa

one tablet t.i.d.

If necessary, to control symptoms, dosage may be increased by one tablet every day or every other day until a dosage of eight tablets of Sinemet 25-100 a day is reached.

2

When it is evident that patients need more levodopa...Transfer to:

SINEMET 25-250

containing 25 mg carbidopa (anhydrous equivalent) and 250 mg levodopa

one tablet t.i.d.

If still more levodopa is necessary, dosage with Sinemet 25-250 may be increased by one-half to one tablet every day or every other day to a maximum of eight tablets a day.

3

When individualizing dosage...Titrate with:

SINEMET 10-100

containing 10 mg carbidopa (anhydrous equivalent) and 100 mg levodopa

or SINEMET 25-100

or SINEMET 25-250

The optimum daily dosage of Sinemet must be determined by careful titration in each patient. Tablets of the three strengths may be given separately or combined as needed to provide the optimum daily dosage.

For patients transferred from levodopa

DISCONTINUE LEVODOPA AT LEAST 8 HOURS BEFORE STARTING SINEMET.

The starting dose for Sinemet should provide about 25 percent of previous levodopa requirements. (Patients receiving less than 1500 mg of levodopa a day should be started on one tablet of Sinemet 25-100 t.i.d. or q.i.d.)

Sinemet®

(Carbidopa-Levodopa)

When SINEMET is to be given to patients who are being treated with levodopa, levodopa must be discontinued at least 8 hours before therapy with SINEMET is started. In order to reduce adverse reactions, it is necessary to individualize therapy. See the WARNINGS (below) and DOSAGE AND ADMINISTRATION sections in the Prescribing Information before initiating therapy.

Contraindications: MAO inhibitors and SINEMET should not be given concomitantly. MAO inhibitors must be discontinued at least 2 weeks prior to initiating therapy with SINEMET.

SINEMET is contraindicated in patients with known hypersensitivity to this drug and in narrow-angle glaucoma.

Because levodopa may activate a malignant melanoma, it should not be used in patients with suspicious, undiagnosed skin lesions or history of melanoma.

Warnings: Levodopa must be discontinued at least 8 hours before SINEMET is started. SINEMET should be substituted at a dosage that will provide approximately 25 percent of the previous levodopa dosage. (See DOSAGE AND ADMINISTRATION section of Prescribing Information.) Patients taking SINEMET should be instructed not to take additional levodopa unless prescribed.

As with levodopa, SINEMET may cause involuntary movements and mental disturbances. These reactions may be due to increased brain dopamine following administration of levodopa. All patients should be observed carefully for development of depression with concomitant suicidal tendencies. Treat with caution patients with past or current psychoses. *Because carbidopa permits more levodopa to reach the brain and, thus, more dopamine to be formed, dyskinesias may occur at lower dosages and sooner with* SINEMET *than with levodopa.* Occurrence of dyskinesias may require dosage reduction.

SINEMET should be administered cautiously to patients with severe cardiovascular or pulmonary disease, bronchial asthma, renal, hepatic or endocrine disease.

Exercise care in administering SINEMET, as with levodopa, to patients with history of myocardial infarction who have residual atrial, nodal, or ventricular arrhythmias. In such patients, cardiac function should be monitored with particular care during period of initial dosage adjustment, in a facility with provisions for intensive cardiac care.

As with levodopa, there is possibility of upper GI hemorrhage in patients with history of peptic ulcer.

A symptom complex resembling the neuroleptic malignant syndrome including muscular rigidity, elevated body temperature, mental changes, and increased serum creatine phosphokinase has been reported when antiparkinsonian agents were withdrawn abruptly. Therefore, patients should be observed carefully when the dosage of SINEMET is reduced abruptly or discontinued, especially if the patient is receiving neuroleptics.

Usage in Pregnancy and Lactation: Although effects of SINEMET on human pregnancy and lactation are unknown, both levodopa and combinations of carbidopa and levodopa have caused visceral and skeletal malformations in rabbits. Use of SINEMET in women of childbearing potential requires that anticipated benefits of the drug be weighed against possible hazards to mother and child. SINEMET should not be given to nursing mothers.

Usage in Children: Safety of SINEMET in patients under 18 has not been established.

Precautions: As with levodopa, periodic evaluations of hepatic, hematopoietic, cardiovascular, and renal function are recommended during extended therapy.

Patients with chronic wide-angle glaucoma may be treated cautiously with SINEMET provided intraocular pressure is well controlled and patient is monitored carefully for changes in intraocular pressure during therapy.

Laboratory Tests: Abnormalities in laboratory tests may include elevations of liver function tests such as alkaline phosphatase, SGOT (AST), SGPT (ALT), lactic dehydrogenase, and bilirubin. Abnormalities in protein-bound iodine, blood urea nitrogen, and positive Coombs test have also been reported. Commonly, levels of blood urea nitrogen, creatinine, and uric acid are lower during administration of SINEMET than with levodopa.

SINEMET may cause a false-positive reaction for urinary ketone bodies when a test tape is used for determination of ketonuria. This reaction will not be altered by boiling the urine specimen. False-negative tests may result with the use of glucose-oxidase methods of testing for glucosuria.

Drug Interactions: Caution should be exercised when the following drugs are administered concomitantly with SINEMET.

Symptomatic postural hypotension can occur when SINEMET is added to the treatment of a patient receiving antihypertensive drugs. Therefore, when therapy with SINEMET is started, dosage adjustment of the antihypertensive drug may be required. For patients receiving monoamine oxidase inhibitors, see CONTRAINDICATIONS (above).

There have been rare reports of adverse reactions, including hypertension and dyskinesia, resulting from the concomitant use of tricyclic antidepressants and SINEMET.

Phenothiazines and butyrophenones may reduce the therapeutic effects of levodopa. In addition, the beneficial effects of levodopa in Parkinson's disease have been reported to be reversed by phenytoin and papaverine. Patients taking these drugs with SINEMET should be carefully observed for loss of therapeutic response.

Adverse Reactions: Most common serious adverse reactions occurring with SINEMET are choreiform, dystonic, and other involuntary movements. Other serious adverse reactions are mental changes including paranoid ideation and psychotic episodes, depression with or without development of suicidal tendencies and dementia. Convulsions also have occurred; however, a causal relationship with SINEMET has not been established.

A common but less serious effect is nausea.

Less frequent adverse reactions are cardiac irregularities and/or palpitation, orthostatic hypotensive episodes, bradykinetic episodes (the "on-off" phenomenon), anorexia, vomiting, and dizziness.

Rarely, GI bleeding, development of duodenal ulcer, hypertension, phlebitis, hemolytic and non-hemolytic anemia, thrombocytopenia, leukopenia, and agranulocytosis have occurred.

Laboratory tests which have been reported to be abnormal are alkaline phosphatase, SGOT (AST), SGPT (ALT), lactic dehydrogenase, bilirubin, blood urea nitrogen, protein-bound iodine, and Coombs test.

Other adverse reactions that have been reported with levodopa are: *Nervous System*: ataxia, numbness, increased hand tremor, muscle twitching, muscle cramps, blepharospasm (which may be taken as an early sign of excess dosage, consideration of dosage reduction may be made at this time), trismus, activation of latent Horner's syndrome. *Psychiatric*: confusion, sleepiness, insomnia, nightmares, hallucinations, delusions, agitation, anxiety, euphoria. *Gastrointestinal*: dry mouth, bitter taste, sialorrhea, dysphagia, bruxism, hiccups, abdominal pain and distress, constipation, diarrhea, flatulence, burning sensation of tongue. *Metabolic*: weight gain or loss, edema. *Integumentary*: malignant melanoma (see also CONTRAINDICATIONS), flushing, increased sweating, dark sweat, skin rash, loss of hair. *Genitourinary*: urinary retention, urinary incontinence, dark urine, priapism. *Special Senses*: diplopia, blurred vision, dilated pupils, oculogyric crises. *Miscellaneous*: weakness, faintness, fatigue, headache, hoarseness, malaise, hot flashes, sense of stimulation, bizarre breathing patterns, neuroleptic malignant syndrome.

Overdosage: Management of acute overdosage with SINEMET is basically the same as management of acute overdosage with levodopa; however, pyridoxine is not effective in reversing the actions of SINEMET.

How Supplied: Tablets SINEMET 10-100, SINEMET 25-100, and SINEMET 25-250 are supplied in bottles of 100 and unit dose packages of 100.

Storage: Tablets SINEMET 10-100 and Tablets SINEMET 25-250 must be protected from light.

SANDOZPHARMACEUTICALS
Corporation, E. Hanover, NJ 07936 (201) 503-7500

BRIEF SUMMARY: Please see package insert for full prescribing information.

FIORINAL® WITH CODEINE CIII CAPSULES

(Codeine phosphate USP, 30 mg [warning: may be habit forming]; butalbital USP, 50 mg [warning: may be habit forming]; caffeine USP, 40 mg; aspirin USP, 325 mg)

CAUTION: Federal law prohibits dispensing without prescription.

CONTRAINDICATIONS: Fiorinal® with Codeine is contraindicated under the following conditions:

1. Hypersensitivity or intolerance to aspirin, caffeine, butalbital or codeine.
2. Patients with a hemorrhagic diathesis (e.g., hemophilia, hypoprothrombinemia, von Willebrand's disease, the thrombocytopenias, thrombasthenia and other ill-defined hereditary platelet dysfunctions, severe vitamin K deficiency and severe liver damage.)
3. Patients with the syndrome of nasal polyps, angioedema and bronchospastic reactivity to aspirin or other nonsteroidal anti-inflammatory drugs. Anaphylactoid reactions have occurred in such patients.
4. Peptic ulcer or other serious gastrointestinal lesions.
5. Patients with porphyria.

WARNINGS: Therapeutic doses of aspirin can cause anaphylactic shock and other severe allergic reactions. It should be ascertained if the patient is allergic to aspirin, although a specific history of allergy may be lacking.

Significant bleeding can result from aspirin therapy in patients with peptic ulcer or other gastrointestinal lesions, and in patients with bleeding disorders.

Aspirin administered pre-operatively may prolong the bleeding time.

In the presence of head injury or other intracranial lesions, the respiratory depressant effects of codeine and other narcotics may be markedly enhanced, as well as their capacity for elevating cerebrospinal fluid pressure. Narcotics also produce other CNS depressant effects, such as drowsiness, that may further obscure the clinical course of patients with head injuries.

Codeine or other narcotics may obscure signs on which to judge the diagnosis or clinical course of patients with acute abdominal conditions.

Butalbital and codeine are both habit-forming and potentially abusable. Consequently, the extended use of Fiorinal® with Codeine is not recommended.

Results from epidemiologic studies indicate an association between aspirin and Reye Syndrome. Caution should be used in administering this product to children, including teenagers, with chicken pox or flu.

PRECAUTIONS: General: Fiorinal® with Codeine should be prescribed with caution for certain special-risk patients such as the elderly or debilitated, and those with severe impairment of renal or hepatic function, coagulation disorders, or head injuries.

Aspirin should be used with caution in patients on anticoagulant therapy and in patients with underlying hemostatic defects.

Precautions should be taken when administering salicylates to persons with known allergies. Hypersensitivity to aspirin is particularly likely in patients with nasal polyps, and relatively common in those with asthma.

Information for Patients: Patients should be informed that Fiorinal® with Codeine contains aspirin and should not be taken by patients with an aspirin allergy.

Fiorinal® with Codeine may impair the mental and/or physical abilities required for performance of potentially hazardous tasks such as driving a car or operating machinery. Such tasks should be avoided while taking Fiorinal® with Codeine.

Alcohol and other CNS depressants may produce an additive CNS depression when taken with Fiorinal® with Codeine, and should be avoided.

Codeine and butalbital may be habit-forming. Patients should take the drug only for as long as it is prescribed, in the amounts prescribed, and no more frequently than prescribed.

Laboratory Tests: In patients with severe hepatic or renal disease, effects of therapy should be monitored with serial liver and/or renal function tests.

Drug Interactions: The CNS effects of butalbital may be enhanced by monoamine oxidase (MAO) inhibitors.

In patients receiving concomitant corticosteroids and chronic use of aspirin, withdrawal of corticosteroids may result in salicylism because corticosteroids enhance renal clearance of salicylates and their withdrawal is followed by return to normal rates of renal clearance.

Fiorinal® with Codeine may enhance the effects of:

1. Oral anticoagulants, causing bleeding by inhibiting prothrombin formation in the liver and displacing anticoagulants from plasma protein binding sites.
2. Oral antidiabetic agents and insulin, causing hypoglycemia by contributing an additive effect, if dosage of Fiorinal® with Codeine exceeds maximum recommended daily dosage.
3. 6-mercaptopurine and methotrexate, causing bone marrow toxicity and blood dyscrasias by displacing these drugs from secondary binding sites, and, in the case of methotrexate, also reducing its excretion.
4. Non-steroidal anti-inflammatory agents, increasing the risk of peptic ulceration and bleeding by contributing additive effects.
5. Other narcotic analgesics, alcohol, general anesthetics, tranquilizers such as chlordiazepoxide, sedative-hypnotics, or other CNS depressants, causing increased CNS depression.

Fiorinal® with Codeine may diminish the effects of: Uricosuric agents such as probenecid and sulfinpyrazone, reducing their effectiveness in the treatment of gout. Aspirin competes with these agents for protein binding sites.

Drug/Laboratory Test Interactions

Aspirin: Aspirin may interfere with the following laboratory determinations in blood: serum amylase, fasting blood glucose, cholesterol, protein, serum glutamic-oxalacetic transaminase (SGOT), uric acid, prothrombin time and bleeding time. Aspirin may interfere with the following laboratory determinations in urine: glucose, 5-hydroxyindoleacetic acid, Gerhardt ketone, vanillylmandelic acid (VMA), uric acid, diacetic acid, and spectrophotometric detection of barbiturates.

Codeine: Codeine may increase serum amylase levels.

Carcinogenesis, Mutagenesis, Impairment of Fertility: Adequate long-term studies have been conducted in mice and rats with aspirin, alone or in combination with other drugs, in which no evidence of carcinogenesis was seen. No adequate studies have been conducted in animals to determine whether aspirin has a potential for mutagenesis or impairment of fertility. No adequate studies have been conducted in animals to determine whether butalbital has a potential for carcinogenesis, mutagenesis, or impairment of fertility.

Usage in Pregnancy

Teratogenic Effects: Pregnancy Category C — Animal reproduction studies have not been conducted with Fiorinal® with Codeine. It is also not known whether Fiorinal® with Codeine can cause fetal harm when administered to a pregnant woman or can affect reproduction capacity. Fiorinal® with Codeine should be given to a pregnant woman only when clearly needed.

Nonteratogenic Effects: Although Fiorinal® with Codeine was not implicated in the birth defect, a female infant was born with lissencephaly, pachygyria and heterotopic gray matter. The infant was born 8 weeks prematurely to a woman who had taken an average of 90 Fiorinal® with Codeine capsules each month from the first few days of pregnancy. The child's development was mildly delayed and from one year of age she had partial simple motor seizures.

Withdrawal seizures were reported in a two-day-old male infant whose mother had taken a butalbital-containing drug during the last 2 months of pregnancy. Butalbital was found in the infant's serum. The infant was given phenobarbital 5mg/kg, which was tapered without further seizure or other withdrawal symptoms.

Studies of aspirin use in pregnant women have not shown that aspirin increases the risk of abnormalities when administered during the first trimester of pregnancy. In controlled studies involving 41,337 pregnant women and their offspring, there was no evidence that aspirin taken during pregnancy caused stillbirth, neonatal death or reduced birth weight. In controlled studies of 50,282 pregnant women and their offspring, aspirin administration in moderate and heavy doses during the first four lunar months of pregnancy showed no teratogenic effect.

Reproduction studies have been performed in rabbits and rats at doses up to 150 times the human dose and have revealed no evidence of impaired fertility or harm to the fetus due to codeine.

Therapeutic doses of aspirin in pregnant women close to term may cause bleeding in mother, fetus, or neonate. During the last 6 months of pregnancy, regular use of aspirin in high doses may prolong pregnancy and delivery.

Labor and Delivery: Ingestion of aspirin prior to delivery may prolong delivery or lead to bleeding in the mother or neonate. Use of codeine during labor may lead to respiratory depression in the neonate.

Nursing Mothers: Aspirin, caffeine, barbiturates and codeine are excreted in breast milk in small amounts, but the significance of their effects on nursing infants is not known. Because of potential for serious adverse reactions in nursing infants from Fiorinal® with Codeine, a decision should be made whether to discontinue nursing or to discontinue the drug, taking into account the importance of the drug to the mother.

Pediatric Use: Safety and effectiveness in children below the age of 12 have not been established.

ADVERSE REACTIONS: Commonly Observed: The most commonly reported adverse events associated with the use of Fiorinal® with Codeine and not reported at an equivalent incidence by placebo-treated patients were nausea and/or abdominal pain, drowsiness, and dizziness.

Associated with Treatment Discontinuation: Of the 382 patients treated with Fiorinal® with Codeine in controlled clinical trials, three (0.8%) discontinued treatment with Fiorinal® with Codeine because of adverse events. One patient each discontinued treatment for the following reasons: gastrointestinal upset; lightheadedness and heavy eyelids; and drowsiness and generalized tingling.

Incidence in Controlled Clinical Trials: The following table summarizes the incidence rates of the adverse events reported by at least 1% of the Fiorinal® with Codeine treated patients in controlled clinical trials comparing Fiorinal® with Codeine to placebo, and provides a comparison to the incidence rates reported by the placebo-treated patients.

The prescriber should be aware that these figures cannot be used to predict the incidence of side effects in the course of usual medical practice where patient characteristics and other factors differ from those that prevailed in the clinical trials. Similarly, the cited frequencies cannot be compared with figures obtained from other clinical investigations involving different treatments, uses, and investigators.

Adverse Events Reported by at Least 1% of Fiorinal® with Codeine Treated Patients During Placebo Controlled Clinical Trials

	Incidence Rate of Adverse Events	
Body System/ Adverse Event	Fiorinal®/Codeine (N = 382)	Placebo (N = 377)
Central Nervous		
Drowsiness	2.4%	0.5%
Dizziness/Lightheadedness	2.6%	0.5%
Intoxicated Feeling	1.0%	0%
Gastrointestinal		
Nausea/Abdominal Pain	3.7%	0.8%

Other Adverse Events Reported During Controlled Clinical Trials: The listing that follows represents the proportion of the 382 patients exposed to Fiorinal® with Codeine while participating in the controlled clinical trials who reported, on at least one occasion, an adverse event of the type cited. All reported adverse events, except those already presented in the previous table, are included. It is important to emphasize that, although the adverse events reported did occur while the patient was receiving Fiorinal® with Codeine, the adverse events were not necessarily caused by Fiorinal® with Codeine.

Adverse events are classified by body system and frequency. "Frequent" is defined as an adverse event which occurred in at least 1/100 (1%) of the patients; all adverse events listed in the previous table are frequent. "Infrequent" is defined as an adverse event that occurred in less than 1/100 patients but at least 1/1000 patients. All adverse events tabulated below are classified as infrequent.

Central Nervous: headache, shaky feeling, tingling, agitation, fainting, fatigue, heavy eyelids, high energy, hot spells, numbness, and sluggishness.

Autonomic Nervous: dry mouth and hyperhidrosis.

Gastrointestinal: vomiting, difficulty swallowing, and heartburn.

Cardiovascular: tachycardia.

Musculoskeletal: leg pain and muscle fatigue.

Genitourinary: diuresis.

Miscellaneous: pruritus, fever, earache, nasal congestion, and tinnitus.

Voluntary reports of adverse drug events, temporally associated with Fiorinal® with Codeine, that have been received since market introduction and that were not reported in clinical trials by the patients treated with Fiorinal® with Codeine, are listed below. Many or most of these events may have no causal relationship with the drug and are listed according to body system.

Central Nervous: Abuse, addiction, anxiety, depression, disorientation, hallucination, hyperactivity, insomnia, libido decrease, nervousness, neuropathy, psychosis, sedation, sexual activity increase, slurred speech, twitching, unconsciousness, vertigo.

Autonomic Nervous: epistaxis, flushing, miosis, salivation.

Gastrointestinal: anorexia, appetite increased, constipation, diarrhea, esophagitis, gastroenteritis, gastrointestinal spasm, hiccup, mouth burning, pyloric ulcer.

Cardiovascular: chest pain, hypotensive reaction, palpitations, syncope.

Skin: erythema, erythema multiforme, exfoliative dermatitis, hives, rash, toxic epidermal necrolysis.

Urinary: kidney impairment, urinary difficulty.

Miscellaneous: allergic reaction, anaphylactic shock, cholangiocarcinoma, drug interaction with erythromycin (stomach upset), edema.

The following adverse drug events may be borne in mind as potential effects of the components of Fiorinal® with Codeine. Potential effects of high dosage are listed in the *OVERDOSAGE* section of this insert.

Aspirin: occult blood loss, hemolytic anemia, iron deficiency anemia, gastric distress, heartburn, nausea, peptic ulcer, prolonged bleeding time, acute airway obstruction, renal toxicity when taken in high doses for prolonged periods, impaired urate excretion, hepatitis.

Caffeine: cardiac stimulation, irritability, tremor, dependence, nephrotoxicity, hyperglycemia.

Codeine: nausea, vomiting, drowsiness, lightheadedness, constipation, pruritus.

DRUG ABUSE AND DEPENDENCE: Fiorinal® with Codeine is controlled by the Drug Enforcement Administration and is classified under Schedule III.

Codeine: Codeine can produce drug dependence of the morphine type and, therefore, has the potential for being abused. Psychological dependence, physical dependence, and tolerance may develop upon repeated administration and it should be prescribed and administered with the same degree of caution appropriate to the use of other oral narcotic medications.

Butalbital: *Barbiturates may be habit forming:* Tolerance, psychological dependence, and physical dependence may occur especially following prolonged use of high doses of barbiturates. The average daily dose for the barbiturate addict is usually about 1,500 mg. As tolerance to barbiturates develops, the amount needed to maintain the same level of intoxication increases; tolerance to a fatal dosage, however, does not increase more than two-fold. As this occurs, the margin between an intoxication dosage and fatal dosage becomes smaller. The lethal dose of a barbiturate is far less if alcohol is also ingested. Major withdrawal symptoms (convulsions and delirium) may occur within 16 hours and last up to 5 days after abrupt cessation of these drugs. Intensity of withdrawal symptoms gradually declines over a period of approximately 15 days. Treatment of barbiturate dependence consists of cautious and gradual withdrawal of the drug. Barbiturate-dependent patients can be withdrawn by using a number of different withdrawal regimens. One method involves initiating treatment at the patient's regular dosage level and gradually decreasing the daily dosage as tolerated by the patient.

OVERDOSAGE: The toxic effects of acute overdosage of Fiorinal® with Codeine capsules are attributable mainly to the barbiturate and codeine components, and, to a lesser extent, aspirin. Because toxic effects of caffeine occur in very high dosages only, the possibility of significant caffeine toxicity from Fiorinal® with Codeine overdosage is unlikely.

Signs and Symptoms: Symptoms attributable to *acute barbiturate poisoning* include drowsiness, confusion, and coma; respiratory depression; hypotension; shock. Symptoms attributable to *acute aspirin poisoning* include hyperpnea; acid-base disturbances with development of metabolic acidosis; vomiting and abdominal pain; tinnitus, hyperthermia; hypoprothrombinemia; restlessness; delirium; convulsions. *Acute caffeine poisoning* may cause insomnia, restlessness, tremor, and delirium; tachycardia and extrasystoles. Symptoms of *acute codeine poisoning* include the triad of: pinpoint pupils, marked depression of respiration, and loss of consciousness. Convulsions may occur.

Treatment: The following paragraphs describe one approach to the treatment of overdose with Fiorinal® with Codeine. However, because strategies for the management of an overdose continually evolve, consultation with a regional poison control center is strongly encouraged.

Treatment consists primarily of management of barbiturate intoxication, reversal of the effects of codeine, and the correction of the acid-base imbalance due to salicylism. Vomiting should be induced mechanically or with emetics in the conscious patient. Gastric lavage may be used if the pharyngeal and laryngeal reflexes are present and if less than 4 hours have elapsed since ingestion. A cuffed endotracheal tube should be inserted before gastric lavage of the unconscious patient and when necessary to provide assisted respiration. Diuresis, alkalinization of the urine, and correction of electrolyte disturbances should be accomplished through administration of intravenous fluids such as 1% sodium bicarbonate and 5% dextrose in water.

Meticulous attention should be given to maintaining adequate pulmonary ventilation. Correction of hypotension may require the administration of levarterenol bitartrate or phenylephrine hydrochloride by intravenous infusion. In severe cases of intoxication, peritoneal dialysis, hemodialysis, or exchange transfusion may be lifesaving. Hypoprothrombinemia should be treated with vitamin K, intravenously.

Methemoglobinemia over 30% should be treated with methylene blue by slow intravenous administration.

Naloxone, a narcotic antagonist, can reverse respiratory depression and coma associated with opioid overdose. Typically, a dose of 0.4 mg to 2 mg is given parenterally and may be repeated if an adequate response is not achieved. Since the duration of action of codeine may exceed that of the antagonist, the patient should be kept under continued surveillance and repeated doses of the antagonist should be administered as needed to maintain adequate respiration. A narcotic antagonist should not be administered in the absence of clinically significant respiratory or cardiovascular depression.

Toxic and Lethal Doses:

Butalbital: toxic dose 1.0 g (adult); lethal dose 2.0-5.0 g
Aspirin: toxic blood level greater than 30 mg/100 mL; lethal dose 10-30 g (adult)
Caffeine: toxic dose greater than 1.0 g; lethal dose unknown
Codeine: lethal dose 0.5-1.0 g (adult)

From refill to refill… which carbamazepine will your patient get next?

TEGRETOL is indicated for children 6 years and older and adults.

Because of the potential for serious hematologic adverse reactions, it is important that you become thoroughly familiar with the full Prescribing Information for TEGRETOL on the following page, especially the boxed warning.

CIBA–GEIGY

Prevent substitution when you prescribe Tegretol

Sign each prescription on the line that prevents substitution, or add the phrase required in your state to prevent substitution:

☐ Dispense As Written
☐ No Substitution
☐ Do Not Substitute
☐ Brand Necessary
☐ No Drug Product Selection
☐ May Not Substitute
☐ Medically Necessary

For your Medicaid patients…

To prevent substitution of TEGRETOL for your Medicaid patients, be sure to add the phrase "Brand Medically Necessary" on each prescription.

Tegretol®
carbamazepine USP

200-mg scored tablets
100-mg chewable tablets

…because there's no substitute for experience.

Tegretol® carbamazepine USP

Chewable Tablets of 100 mg—red-speckled, pink **Tablets of 200 mg—pink**

WARNING

APLASTIC ANEMIA AND AGRANULOCYTOSIS HAVE BEEN REPORTED IN ASSOCIATION WITH THE USE OF TEGRETOL. DATA FROM A POPULATION-BASED CASE CONTROL STUDY DEMONSTRATE THAT THE RISK OF DEVELOPING THESE REACTIONS IS 5-8 TIMES GREATER THAN IN THE GENERAL POPULATION. HOWEVER, THE OVERALL RISK OF THESE REACTIONS IN THE UNTREATED GENERAL POPULATION IS LOW. APPROXIMATELY SIX PATIENTS PER ONE MILLION POPULATION PER YEAR FOR AGRANULOCYTOSIS AND TWO PATIENTS PER ONE MILLION POPULATION PER YEAR FOR APLASTIC ANEMIA.

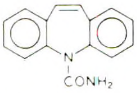
ALTHOUGH REPORTS OF TRANSIENT OR PERSISTENT DECREASED PLATELET OR WHITE BLOOD CELL COUNTS ARE NOT UNCOMMON IN ASSOCIATION WITH THE USE OF TEGRETOL, DATA ARE NOT AVAILABLE TO ESTIMATE ACCURATELY THEIR INCIDENCE OR OUTCOME. HOWEVER, THE VAST MAJORITY OF THE CASES OF LEUKOPENIA HAVE NOT PROGRESSED TO THE MORE SERIOUS CONDITIONS OF APLASTIC ANEMIA OR AGRANULOCYTOSIS.

BECAUSE OF THE VERY LOW INCIDENCE OF AGRANULOCYTOSIS AND APLASTIC ANEMIA, THE VAST MAJORITY OF MINOR HEMATOLOGIC CHANGES OBSERVED IN MONITORING OF PATIENTS ON TEGRETOL ARE UNLIKELY TO SIGNAL THE OCCURRENCE OF EITHER ABNORMALITY. NONETHELESS, COMPLETE PRETREATMENT HEMATOLOGICAL TESTING SHOULD BE OBTAINED AS A BASELINE. IF A PATIENT IN THE COURSE OF TREATMENT EXHIBITS LOW OR DECREASED WHITE BLOOD CELL OR PLATELET COUNTS, THE PATIENT SHOULD BE MONITORED CLOSELY. DISCONTINUATION OF THE DRUG SHOULD BE CONSIDERED IF ANY EVIDENCE OF SIGNIFICANT BONE MARROW DEPRESSION DEVELOPS.

Before prescribing Tegretol, the physician should be thoroughly familiar with the details of this prescribing information, particularly regarding use with other drugs, especially those which accentuate toxicity potential.

DESCRIPTION

Tegretol, carbamazepine USP, is an anticonvulsant and specific analgesic for trigeminal neuralgia, available as chewable tablets of 100 mg and tablets of 200 mg for oral administration. Its chemical name is 5H-dibenz [b,f]azepine-5-carboxamide, and its structural formula is:



Carbamazepine USP is a white to off-white powder, practically insoluble in water and soluble in alcohol and in acetone. Its molecular weight is 236.27.

Inactive Ingredients. Colloidal silicon dioxide, FD&C Red No. 3 (chewable tablets only), FD&C Red No. 40 (200-mg tablets only), flavoring (chewable tablets only), gelatin, glycerin, magnesium stearate, sodium starch glycolate (chewable tablets only), starch, stearic acid, and sucrose (chewable tablets only).

CLINICAL PHARMACOLOGY

In controlled clinical trials, Tegretol has been shown to be effective in the treatment of psychomotor and grand mal seizures, as well as trigeminal neuralgia.

It has demonstrated anticonvulsant properties in rats and mice with electrically and chemically induced seizures. It appears to act by reducing polysynaptic responses and blocking the posttetanic potentiation. Tegretol greatly reduces or abolishes pain induced by stimulation of the infraorbital nerve in cats and rats. It depresses thalamic potential and bulbar and polysynaptic reflexes, including the linguomandibular reflex in cats. Tegretol is chemically unrelated to other anticonvulsants or other drugs used to control the pain of trigeminal neuralgia. The mechanism of action remains unknown.

Tegretol tablets are adequately absorbed after oral administration at a slower rate than a solution, thus avoiding undesirably high peak concentrations. Tegretol chewable tablets may produce higher peak levels than the same dose given as regular tablets. Tegretol in blood is 76% bound to plasma proteins. Plasma levels of Tegretol are variable and may range from 0.5-25 μg/ml, with no apparent relationship to the daily intake of the drug. Usual adult therapeutic levels are between 4 and 12 μg/ml. Following oral administration, serum levels peak at 4 to 5 hours. The CSF/serum ratio is 0.22, similar to the 22% unbound Tegretol in serum. Because Tegretol may induce its own metabolism, the half-life is also variable. Initial half-life values range from 25-65 hours, with 12-17 hours on repeated doses. Tegretol is metabolized in the liver. After oral administration of 14C-carbamazepine, 72% of the administered radioactivity was found in the urine and 28% in the feces. This urinary radioactivity was composed largely of hydroxylated and conjugated metabolites, with only 3% of unchanged Tegretol. Transplacental passage of Tegretol is rapid (30 to 60 minutes), and the drug is accumulated in fetal tissues, with higher levels found in liver and kidney than in brain and lungs.

INDICATIONS AND USAGE

Epilepsy: Tegretol is indicated for use as an anticonvulsant drug. Evidence supporting efficacy of Tegretol as an anticonvulsant was derived from active drug-controlled studies that enrolled patients with the following seizure types:

1. Partial seizures with complex symptomatology (psychomotor, temporal lobe). Patients with these seizures appear to show greater improvement than those with other types.
2. Generalized tonic-clonic seizures (grand mal).
3. Mixed seizure patterns which include the above, or other partial or generalized seizures.

Absence seizures (petit mal) do not appear to be controlled by Tegretol (see PRECAUTIONS, General).

Trigeminal Neuralgia: Tegretol is indicated in the treatment of the pain associated with true trigeminal neuralgia.

Beneficial results have also been reported in glossopharyngeal neuralgia.

This drug is not a simple analgesic and should not be used for the relief of trivial aches or pains.

CONTRAINDICATIONS

Tegretol should not be used in patients with a history of previous bone marrow depression, hypersensitivity to the drug, or known sensitivity to any of the tricyclic compounds, such as amitriptyline, desipramine, imipramine, protriptyline, nortriptyline, etc. Likewise, on theoretical grounds its use with monoamine oxidase inhibitors is not recommended. Before administration of Tegretol, MAO inhibitors should be discontinued for a minimum of fourteen days, or longer if the clinical situation permits.

WARNINGS

Patients with a history of adverse hematologic reaction to any drug may be particularly at risk.

Severe dermatologic reactions including toxic epidermal necrolysis (Lyell's syndrome) and Stevens-Johnson syndrome, have been reported with Tegretol. These reactions have been extremely rare. However, a few fatalities have been reported.

Tegretol has shown mild anticholinergic activity; therefore, patients with increased intraocular pressure should be closely observed during therapy.

Because of the relationship of the drug to other tricyclic compounds, the possibility of activation of a latent psychosis and, in elderly patients, of confusion or agitation should be borne in mind.

PRECAUTIONS

General: Before initiating therapy, a detailed history and physical examination should be made.

Tegretol should be used with caution in patients with a mixed seizure disorder that includes atypical absence seizures, since in these patients Tegretol has been associated with increased frequency of generalized convulsions (see INDICATIONS AND USAGE).

Therapy should be prescribed only after critical benefit-to-risk appraisal in patients with a history of cardiac, hepatic or renal damage, adverse hematologic reaction to other drugs, or interrupted courses of therapy with Tegretol.

Information for Patients: Patients should be made aware of the early toxic signs and symptoms of a potential hematologic problem, such as fever, sore throat, ulcers in the mouth, easy bruising, petechial or purpuric hemorrhage, and should be advised to report to the physician immediately if any such signs or symptoms appear.

Since dizziness and drowsiness may occur, patients should be cautioned about the hazards of operating machinery or automobiles or engaging in other potentially dangerous tasks.

Laboratory Tests: Complete pretreatment blood counts, including platelets and possibly reticulocytes and serum iron, should be obtained as a baseline. If a patient in the course of treatment exhibits low or decreased white blood cell or platelet counts, the patient should be monitored closely. Discontinuation of the drug should be considered if any evidence of significant bone marrow depression develops.

Baseline and periodic evaluations of liver function, particularly in patients with a history of liver disease, must be performed during treatment with this drug since liver damage may occur. The drug should be discontinued immediately in cases of aggravated liver dysfunction or active liver disease.

Baseline and periodic eye examinations, including slit-lamp, funduscopy and tonometry, are recommended since many phenothiazines and related drugs have been shown to cause eye changes.

Baseline and periodic complete urinalysis and BUN determinations are recommended for patients treated with this agent because of observed renal dysfunction.

Monitoring of blood levels (see CLINICAL PHARMACOLOGY) has increased the efficacy and safety of anticonvulsants. This monitoring may be particularly useful in cases of dramatic increase in seizure frequency and for verification of compliance. In addition, measurement of drug serum levels may aid in determining the cause of toxicity when more than one medication is being used.

Thyroid function tests have been reported to show decreased values with Tegretol administered alone.

Hyponatremia has been reported in association with Tegretol use, either alone or in combination with other drugs.

Drug Interactions: The simultaneous administration of phenobarbital, phenytoin, or primidone, or a combination of two, produces a marked lowering of serum levels of Tegretol. The effect of valproic acid on Tegretol blood levels is not clearly established, although an increase in the ratio of active 10, 11-epoxide metabolite to parent compound is a consistent finding.

The half-lives of phenytoin, warfarin, doxycycline, and theophylline were significantly shortened when administered concurrently with Tegretol. Haloperidol and valproic acid serum levels may be reduced when these drugs are administered with Tegretol. The doses of these drugs may therefore have to be increased when Tegretol is added to the therapeutic regimen.

Concomitant administration of Tegretol with erythromycin, cimetidine, propoxyphene, isoniazid or calcium channel blockers has been reported to result in elevated plasma levels of carbamazepine resulting in toxicity in some cases. Also, concomitant administration of carbamazepine and lithium may increase the risk of neurotoxic side effects.

Alterations of thyroid function have been reported in combination therapy with other anticonvulsant medications.

Breakthrough bleeding has been reported among patients receiving concomitant oral contraceptives and their reliability may be adversely affected.

Carcinogenesis, Mutagenesis, Impairment of Fertility: Carbamazepine, when administered to Sprague-Dawley rats for two years in the diet at doses of 25, 75, and 250 mg/kg/day, resulted in a dose-related increase in the incidence of hepatocellular tumors in females and of benign interstitial cell adenomas in the testes of males.

Carbamazepine must, therefore, be considered to be carcinogenic in Sprague-Dawley rats. Bacterial and mammalian mutagenicity studies using carbamazepine produced negative results. The significance of these findings relative to the use of carbamazepine in humans is, at present, unknown.

Pregnancy Category C: Tegretol has been shown to have adverse effects in reproduction studies in rats when given orally in dosages 10-25 times the maximum human daily dosage of 1200 mg. In rat teratology studies, 2 of 135 offspring showed kinked ribs at 250 mg/kg and 4 of 119 offspring at 650 mg/kg showed other anomalies (cleft palate, 1; talipes, 1; anophthalmos, 2). In reproduction studies in rats, nursing offspring demonstrated a lack of weight gain and an unkempt appearance at a maternal dosage level of 200 mg/kg.

There are no adequate and well-controlled studies in pregnant women. Epidemiological data suggest that there may be an association between the use of carbamazepine during pregnancy and congenital malformations, including spina bifida. Tegretol should be used during pregnancy only if the potential benefit justifies the potential risk to the fetus.

Retrospective case reviews suggest that, compared with monotherapy, there may be a higher prevalence of teratogenic effects associated with the use of anticonvulsants in combination therapy. Therefore, monotherapy is recommended for pregnant women.

It is important to note that anticonvulsant drugs should not be discontinued in patients in whom the drug is administered to prevent major seizures because of the strong possibility of precipitating status epilepticus with attendant hypoxia and threat to life. In individual cases where the severity and frequency of the seizure disorder are such that removal of medication does not pose a serious threat to the patient, discontinuation of the drug may be considered prior to and during pregnancy, although it cannot be said with any confidence that even minor seizures do not pose some hazard to the developing embryo or fetus.

Only TEGRETOL,
brand of carbamazepine,
provides the prescribing
flexibility of a 100-mg scored
chewable tablet, as well as
a 200-mg scored tablet.

Labor and Delivery: The effect of Tegretol on human labor and delivery is unknown.

Nursing Mothers: During lactation, concentration of Tegretol in milk is approximately 60% of the maternal plasma concentration.

Because of the potential for serious adverse reactions in nursing infants from carbamazepine, a decision should be made whether to discontinue nursing or to discontinue the drug, taking into account the importance of the drug to the mother.

Pediatric Use: Safety and effectiveness in children below the age of 6 years have not been established.

ADVERSE REACTIONS

If adverse reactions are of such severity that the drug must be discontinued, the physician must be aware that abrupt discontinuation of any anticonvulsant drug in a responsive epileptic patient may lead to seizures or even status epilepticus with its life-threatening hazards.

The most severe adverse reactions have been observed in the hemopoietic system (see boxed WARNING), the skin and the cardiovascular system.

The most frequently observed adverse reactions, particularly during the initial phases of therapy, are dizziness, drowsiness, unsteadiness, nausea, and vomiting. To minimize the possibility of such reactions, therapy should be initiated at the low dosage recommended.

The following additional adverse reactions have been reported:

Hemopoietic System: Aplastic anemia, agranulocytosis, pancytopenia, bone marrow depression, thrombocytopenia, leukopenia, leukocytosis, eosinophilia, acute intermittent porphyria.

Skin: Pruritic and erythematous rashes, urticaria, toxic epidermal necrolysis (Lyell's syndrome) (see WARNINGS), Stevens-Johnson syndrome (see WARNINGS), photosensitivity reactions, alterations in skin pigmentation, exfoliative dermatitis, erythema multiforme and nodosum, purpura, aggravation of disseminated lupus erythematosus, alopecia, and diaphoresis. In certain cases, discontinuation of therapy may be necessary.

Cardiovascular System: Congestive heart failure, edema, aggravation of hypertension, hypotension, syncope and collapse, aggravation of coronary artery disease, arrhythmias and AV block, primary thrombophlebitis, recurrence of thrombophlebitis, and adenopathy or lymphadenopathy.

Some of these cardiovascular complications have resulted in fatalities. Myocardial infarction has been associated with other tricyclic compounds.

Liver: Abnormalities in liver function tests, cholestatic and hepatocellular jaundice, hepatitis.

Respiratory System: Pulmonary hypersensitivity characterized by fever, dyspnea, pneumonitis or pneumonia.

Genitourinary System: Urinary frequency, acute urinary retention, oliguria with elevated blood pressure, azotemia, renal failure, and impotence. Albuminuria, glycosuria, elevated BUN and microscopic deposits in the urine have also been reported.

Testicular atrophy occurred in rats receiving Tegretol orally from 4 to 52 weeks at dosage levels of 50 to 400 mg/kg/day. Additionally, rats receiving Tegretol in the diet for two years at dosage levels of 25, 75, and 250 mg/kg/day had a dose-related incidence of testicular atrophy and aspermatogenesis. In dogs, it produced a brownish discoloration, presumably a metabolite, in the urinary bladder at dosage levels of 50 mg/kg and higher. Relevance of these findings to humans is unknown.

Nervous System: Dizziness, drowsiness, disturbances of coordination, confusion, headache, fatigue, blurred vision, visual hallucinations, transient diplopia, oculomotor disturbances, nystagmus, speech disturbances, abnormal involuntary movements, peripheral neuritis and paresthesias, depression with agitation, talkativeness, tinnitus, and hyperacusis.

There have been reports of associated paralysis and other symptoms of cerebral arterial insufficiency, but the exact relationship of these reactions to the drug has not been established.

Digestive System: Nausea, vomiting, gastric distress and abdominal pain, diarrhea, constipation, anorexia, and dryness of the mouth and pharynx, including glossitis and stomatitis.

Eyes: Scattered, punctate, cortical lens opacities, as well as conjunctivitis have been reported. Although a direct causal relationship has not been established, many phenothiazines and related drugs have been shown to cause eye changes.

Musculoskeletal System: Aching joints and muscles, and leg cramps.

Metabolism: Fever and chills. Inappropriate antidiuretic hormone (ADH) secretion syndrome has been reported. Cases of frank water intoxication, with decreased serum sodium (hyponatremia) and confusion, have been reported in association with Tegretol use (see PRECAUTIONS, Laboratory Tests).

Other: Isolated cases of a lupus erythematosus-like syndrome have been reported. There have been occasional reports of elevated levels of cholesterol, HDL cholesterol and triglycerides in patients taking anticonvulsants.

A case of aseptic meningitis, accompanied by myoclonus and peripheral eosinophilia, has been reported in a patient taking carbamazepine in combination with other medications. The patient was successfully dechallenged, and the meningitis reappeared upon rechallenge with carbamazepine.

DRUG ABUSE AND DEPENDENCE

No evidence of abuse potential has been associated with Tegretol, nor is there evidence of psychological or physical dependence in humans.

OVERDOSAGE

Acute Toxicity

Lowest known lethal dose: adults, >60 g (39-year-old man). Highest known doses survived: adults, 30 g (31-year-old woman); children, 10 g (6-year-old boy); small children, 5 g (3-year-old girl).

Oral LD 50 in animals (mg/kg): mice, 1100-3750; rats, 3850-4025; rabbits, 1500-2680; guinea pigs, 920.

Signs and Symptoms

The first signs and symptoms appear after 1-3 hours. Neuromuscular disturbances are the most prominent. Cardiovascular disorders are generally milder, and severe cardiac complications occur only when very high doses (>60 g) have been ingested.

Respiration: Irregular breathing, respiratory depression.

Cardiovascular System: Tachycardia, hypotension or hypertension, shock, conduction disorders.

Nervous System and Muscles: Impairment of consciousness ranging in severity to deep coma. Convulsions, especially in small children. Motor restlessness, muscular twitching, tremor, athetoid movements, opisthotonos, ataxia, drowsiness, dizziness, mydriasis, nystagmus, adiadochokinesia, ballism, psychomotor disturbances, dysmetria. Initial hyperreflexia, followed by hyporeflexia.

Gastrointestinal Tract: Nausea, vomiting.

Kidneys and Bladder: Anuria or oliguria, urinary retention.

Laboratory Findings: Isolated instances of overdosage have included leukocytosis, reduced leukocyte count, glycosuria and acetonuria. EEG may show dysrhythmias.

Combined Poisoning: When alcohol, tricyclic antidepressants, barbiturates or hydantoins are taken at the same time, the signs and symptoms of acute poisoning with Tegretol may be aggravated or modified.

Treatment

The prognosis in cases of severe poisoning is critically dependent upon prompt elimination of the drug, which may be achieved by inducing vomiting, irrigating the stomach, and by taking appropriate steps to diminish absorption. If these measures cannot be implemented without risk on the spot, the patient should be transferred at once to a hospital, while ensuring that vital functions are safeguarded. There is no specific antidote.

Elimination of the Drug: Induction of vomiting.

Gastric lavage. Even when more than 4 hours have elapsed following ingestion of the drug, the stomach should be repeatedly irrigated, especially if the patient has also consumed alcohol.

Measures to Reduce Absorption: Activated charcoal, laxatives.

Measures to Accelerate Elimination: Forced diuresis.

Dialysis is indicated only in severe poisoning associated with renal failure. Replacement transfusion is indicated in severe poisoning in small children.

Respiratory Depression: Keep the airways free; resort, if necessary, to endotracheal intubation, artificial respiration, and administration of oxygen.

Hypotension, Shock: Keep the patient's legs raised and administer a plasma expander. If blood pressure fails to rise despite measures taken to increase plasma volume, use of vasoactive substances should be considered.

Convulsions: Diazepam or barbiturates.

Warning: Diazepam or barbiturates may aggravate respiratory depression (especially in children), hypotension, and coma. However, barbiturates should not be used if drugs that inhibit monoamine oxidase have also been taken by the patient either in overdosage or in recent therapy (within one week).

Surveillance: Respiration, cardiac function (ECG monitoring), blood pressure, body temperature, pupillary reflexes, and kidney and bladder function should be monitored for several days.

Treatment of Blood Count Abnormalities: If evidence of significant bone marrow depression develops, the following recommendations are suggested: (1) stop the drug, (2) perform daily CBC, platelet and reticulocyte counts, (3) do a bone marrow aspiration and trephine biopsy immediately and repeat with sufficient frequency to monitor recovery.

Special periodic studies might be helpful as follows: (1) white cell and platelet antibodies, (2) 59Fe—ferrokinetic studies, (3) peripheral blood cell typing, (4) cytogenetic studies on marrow and peripheral blood, (5) bone marrow culture studies for colony-forming units, (6) hemoglobin electrophoresis for A_2 and F hemoglobin, and (7) serum folic acid and B_{12} levels.

A fully developed aplastic anemia will require appropriate, intensive monitoring and therapy, for which specialized consultation should be sought.

DOSAGE AND ADMINISTRATION

Monitoring of blood levels has increased the efficacy and safety of anticonvulsants (see PRECAUTIONS, Laboratory Tests). Dosage should be adjusted to the needs of the individual patient. A low initial daily dosage with a gradual increase is advised. As soon as adequate control is achieved, the dosage may be reduced very gradually to the minimum effective level. Tablets should be taken with meals.

Epilepsy (see INDICATIONS AND USAGE).

Adults and children over 12 years of age—Initial: 200 mg b.i.d. Increase at weekly intervals by adding up to 200 mg per day using a t.i.d. or q.i.d. regimen until the best response is obtained. Dosage should generally not exceed 1000 mg daily in children 12 to 15 years of age, and 1200 mg daily in patients above 15 years of age. Doses up to 1600 mg daily have been used in adults in rare instances. ***Maintenance:*** Adjust dosage to the minimum effective level, usually 800-1200 mg daily.

Children 6-12 years of age—Initial: 100 mg b.i.d. Increase at weekly intervals by adding 100 mg per day using a t.i.d. or q.i.d. regimen until the best response is obtained. Dosage should generally not exceed 1000 mg. ***Maintenance:*** Adjust dosage to the minimum effective level, usually 400-800 mg daily.

Combination Therapy: Tegretol may be used alone or with other anticonvulsants. When added to existing anticonvulsant therapy, the drug should be added gradually while the other anticonvulsants are maintained or gradually decreased, except phenytoin, which may have to be increased (see PRECAUTIONS, Drug Interactions and Pregnancy Category C).

Trigeminal Neuralgia (see INDICATIONS AND USAGE).

Initial: 100 mg b.i.d. on the first day for a total daily dose of 200 mg. This daily dose may be increased by up to 200 mg a day using increments of 100 mg every 12 hours only as needed to achieve freedom from pain. Do not exceed 1200 mg daily.

Maintenance: Control of pain can be maintained in most patients with 400 mg to 800 mg daily. However, some patients may be maintained on as little as 200 mg daily, while others may require as much as 1200 mg daily. At least once every 3 months throughout the treatment period, attempts should be made to reduce the dose to the minimum effective level or even to discontinue the drug.

HOW SUPPLIED

Chewable Tablets 100 mg—round, red-speckled, pink, single-scored (imprinted Tegretol on one side and 52 twice on the scored side)

Bottles of 100	NDC 0028-0052-01
Unit Dose (blister pack) Box of 100 (strips of 10)	NDC 0028-0052-61

Tablets 200 mg—capsule-shaped, pink, single-scored (imprinted Tegretol on one side and 27 twice on the scored side)

Bottles of 100	NDC 0028-0027-01
Bottles of 1000	NDC 0028-0027-10
Gy-Pak®—One Unit 12 bottles—100 tablets each	NDC 0028-0027-65
Unit Dose (blister pack) Box of 100 (strips of 10)	NDC 0028-0027-61

Samples, when available, are identified by the word *SAMPLE* appearing on each tablet.

Protect from moisture.

Dispense in tight container (USP).

Also available as: Tegretol suspension 100 mg/5 ml, in 450 ml bottles.

Printed in U.S.A. C90-34 (Rev. 6/90)

CALENDAR OF MEETINGS

1991		
Feb	2-3	Sixth Annual Neuroradiology Review Course, Hyatt Regency, Bethesda, Md. Contact Wendy S. Baker, Course Coordinator, Armed Forces Institute of Pathology, Washington, DC 20306-6000; (202) 576-2162.
	2-9	Second Annual Clinical Magnetic Resonance Imaging Meeting, Marriott's Mark Resort, Vail, Colo. Contact Program Coordinator, Department of Radiology, Program Committee, Box 17241, Tampa, FL 33682-7241; (813) 873-2090 or (800) 338-5901.
	8-10	"Clinical Neurology for Psychiatrists," Bahia Mar Resort, Ft Lauderdale, Fla. Contact Office of Continuing Medical Education, Albert Einstein College of Medicine / Montefiore Medical Center, 111 E 210th St, Bronx, NY 10461; (212) 920-6676.
	14-16	Annual Meeting of the Western Electroencephalographic Society, Portland Ore. Contact Bonnie Becker, Executive Secretary, Good Samaritan Hospital, Suite 400, 1040 NW 22nd Ave, Portland, OR 97210; (503) 229-7721.
	15-17	Sixth Meeting of The International Study Group of the Pharmacology of Memory Disorders Associated with Aging, Zurich, Switzerland. Contact Professor Richard J. Wurtman, Bldg E25-604, Whitaker College, Massachusetts Institute of Technology, Cambridge, MA 02139.
	15-17	The 24th Annual Recent Advances in Neurology, San Francisco, Calif. Contact Extended Programs in Medical Education, University of California, Room C-124, San Francisco, CA 94143-0742; (415) 476-4251.
	18-20	Fifth International Symposium on Intracranial Hemodynamics: Transcranial Doppler and Cerebral Blood Flow and Other Modalities, Hyatt Regency Embarcadero Center, San Francisco, Calif. Contact Conference Coordinator, Institute of Applied Physiology and Medicine, 701 16th Ave, Seattle, WA 98122; (206) 442-7330.
	20-23	"The Practicing Physician's Approach to the Difficult Headache Patient," Wyndham Hotel, Palm Springs, Calif. Contact Ms Idell Applebaum, Diamond Headache Clinic Research and Educational Foundation, 5252 N Western Ave, Chicago, IL 60625; (312) 878-5558.
	22-24	"Clinical Neurology for Psychiatrists," Fisherman's Wharf Holiday Inn, San Francisco, Calif. Contact Office of Continuing Medical Education, Albert Einstein College of Medicine / Montefiore Medical Center, 111 E 210th St, Bronx, NY 10461; (212) 920-6676.
March	7-9	"Recent Advances in Geriatric Medicine, New Treatment Options for Old Problems," The Pan Pacific Hotel, San Diego, Calif. Contact Cass Jones, Professional Conference Management Inc, 7916 Convoy Ct, San Diego, CA 92111; (619) 565-9921.
	14-16	"Brain Chemistry and Behavior: Advances in Positron Emission Tomography and Single Photon Emission Tomography Imaging," Baltimore, Md. Contact Patty Campbell, Program Coordinator, The Johns Hopkins Medical Institutions, Office of Continuing Education, 720 Rutland Ave, Baltimore, MD 21205; (301) 955-3839.
	16-20	Fifth Annual Magnetic Resonance Imaging Conference, Marriott's Camelback Inn, Scottsdale, Ariz. Contact Kevin King, Education Coordinator, Radiologic Education Center, St Joseph's Hospital and Medical Center, 350 W Thomas Rd, Phoenix, AZ 85013; (602) 285-3956.
	17-21	The Eighth Conference of the Southeast European Society for Neurology and Psychiatry, Jerusalem, Israel. Contact Shaul Feldman, MD, PO Box 50006, Tel Aviv 61500, Israel.
	17-23	24th Latin American Congress of Neurosurgery, Miami, Fla. Contact Sergio Gonzalez-Arias, MD, 8950 N Kendall Dr, Suite 406, Miami, FL 33176; (305) 271-6159.
	18-20	"Spectrum of Developmental Disabilities: Cerebral Palsy: Issues of Early Detection and Intervention," The Johns Hopkins Medical Institutions, Baltimore, Md. When the world turns upside down...

Transderm Scōp is the better choice for motion sickness prevention

- more effective than 25 mg meclizine and Dramamine®[1,2]
- better compliance because transdermal delivery is more convenient

Transderm Scōp®
scopolamine
programmed delivery
0.5 mg over 72 hrs

Transderm Scōp should not be used in children. Use with special care in the elderly and in patients taking drugs (including alcohol) capable of causing CNS effects. Dryness of the mouth occurs in about two thirds of people. Please see Prescribing Information on next page before prescribing.

CIBA

Transderm Scōp®

scopolamine
(formerly Transderm-V)

Transdermal Therapeutic System

Programmed delivery *in vivo* of 0.5 mg of scopolamine over 3 days

BRIEF SUMMARY (FOR FULL PRESCRIBING INFORMATION, SEE PACKAGE INSERT)

INDICATIONS AND USAGE
Transderm Scōp is indicated for prevention of nausea and vomiting associated with motion sickness in adults. The disc should be applied only to skin in the postauricular area.

Clinical Results: Transderm Scōp provides antiemetic protection within several hours following application of the disc behind the ear. In 195 adult subjects of different racial origins who participated in clinical efficacy studies at sea or in a controlled motion environment, there was a 75% reduction in the incidence of motion-induced nausea and vomiting. Transderm Scōp provided significantly greater protection than that obtained with oral dimenhydrinate.

CONTRAINDICATIONS
Transderm Scōp should not be used in patients with known hypersensitivity to scopolamine or any of the components of the adhesive matrix making up the therapeutic system, or in patients with glaucoma.

WARNINGS
Transderm Scōp should not be used in children and should be used with special caution in the elderly. See **PRECAUTIONS.**

Since drowsiness, disorientation, and confusion may occur with the use of scopolamine, patients should be warned of the possibility and cautioned against engaging in activities that require mental alertness, such as driving a motor vehicle or operating dangerous machinery.

Potentially alarming idiosyncratic reactions may occur with ordinary therapeutic doses of scopolamine.

PRECAUTIONS
General
Scopolamine should be used with caution in patients with pyloric obstruction, or urinary bladder neck obstruction. Caution should be exercised when administering an antiemetic or antimuscarinic drug to patients suspected of having intestinal obstruction.

Transderm Scōp should be used with special caution in the elderly or in individuals with impaired metabolic, liver, or kidney functions, because of the increased likelihood of CNS effects.

Information for Patients
Since scopolamine can cause temporary dilation of the pupils and blurred vision if it comes in contact with the eyes, patients should be strongly advised to wash their hands thoroughly with soap and water immediately after handling the disc.

Patients should be advised to remove the disc immediately and contact a physician in the unlikely event that they experience symptoms of acute narrow-angle glaucoma (pain in and reddening of the eyes accompanied by dilated pupils).

Patients should be warned against driving a motor vehicle or operating dangerous machinery. A patient brochure is available.

Drug Interactions
Scopolamine should be used with care in patients taking drugs, including alcohol, capable of causing CNS effects. Special attention should be given to drugs having anticholinergic properties, e.g., belladonna alkaloids, antihistamines (including meclizine), and antidepressants.

Carcinogenesis, Mutagenesis, Impairment of Fertility
No long-term studies in animals have been performed to evaluate carcinogenic potential. Fertility studies were performed in female rats and revealed no evidence of impaired fertility or harm to the fetus due to scopolamine hydrobromide administered by daily subcutaneous injection. In the highest-dose group (plasma level approximately 500 times the level achieved in humans using a transdermal system), reduced maternal body weights were observed.

Pregnancy Category C
Teratogenic studies were performed in pregnant rats and rabbits with scopolamine hydrobromide administered by daily intravenous injection. No adverse effects were recorded in the rats. In the rabbits, the highest dose (plasma level approximately 100 times the level achieved in humans using a transdermal system) of drug administered had a marginal embryotoxic effect. Transderm Scōp should be used during pregnancy only if the anticipated benefit justifies the potential risk to the fetus.

Nursing Mothers
It is not known whether scopolamine is excreted in human milk. Because many drugs are excreted in human milk, caution should be exercised when Transderm Scōp is administered to a nursing woman.

Pediatric Use
Children are particularly susceptible to the side effects of belladonna alkaloids. Transderm Scōp should not be used in children because it is not known whether this system will release an amount of scopolamine that could produce serious adverse effects in children.

ADVERSE REACTIONS
The most frequent adverse reaction to Transderm Scōp is dryness of the mouth. This occurs in about two thirds of the people. A less frequent adverse reaction is drowsiness, which occurs in less than one sixth of the people. Transient impairment of eye accommodation, including blurred vision and dilation of the pupils, is also observed.

The following adverse reactions have also been reported on infrequent occasions during the use of Transderm Scōp: disorientation; memory disturbances; dizziness; restlessness; hallucinations; confusion; difficulty urinating; rashes and erythema; acute narrow-angle glaucoma; and dry, itchy, or red eyes.

Drug Withdrawal: Symptoms including dizziness, nausea, vomiting, headache and disturbances of equilibrium have been reported in a few patients following discontinuation of the use of the Transderm Scōp system. These symptoms have occurred most often in patients who have used the systems for more than three days.

OVERDOSAGE
Overdosage with scopolamine may cause disorientation, memory disturbances, dizziness, restlessness, hallucinations, or confusion. Should these symptoms occur, the Transderm Scōp disc should be immediately removed. Appropriate parasympathomimetic therapy should be initiated if these symptoms are severe.

DOSAGE AND ADMINISTRATION
Initiation of Therapy: One Transderm Scōp disc (programmed to deliver 0.5 mg of scopolamine over 3 days) should be applied to the hairless area behind one ear at least 4 hours before the antiemetic effect is required. Only one disc should be worn at any time.

Handling: *After the disc is applied on dry skin behind the ear, the hands should be washed thoroughly with soap and water and dried. Upon removal of the disc, it should be discarded, and the hands and application site washed thoroughly with soap and water and dried, to prevent any traces of scopolamine from coming into direct contact with the eyes. (A patient brochure is available.)*

Continuation of Therapy: Should the disc become displaced, it should be discarded, and a fresh one placed on the hairless area behind the other ear. If therapy is required for longer than 3 days, the first disc should be discarded, and a fresh one placed on the hairless area behind the other ear.

The system should be stored between 59°-86°F (15°-30°C).

CAUTION
Federal law prohibits dispensing without prescription.

Books

Mutism: Studies in Disorders of Communication, by Yvan Lebrun, 124 pp, $29, London, England, Whurr Publishers, 1990.

Lebrun's short monograph offers a readable overview of mutism in all of its aspects. The text presents a wide-ranging pastiche of sundry "condition[s] in which there is no, or very little, oral-verbal expression, whilst comprehension . . . is normal or at least at a considerably higher level than oral-verbal output" (p 1). Organized into a short chapter on the psychology of silence and two longer chapters on functional mutism and organic mutism, the book is significant more for its breadth than for its depth. The text is amply referenced and has a useful subject and author index.

Topics, almost dazzling in their variety, range from akinetic mutism to aphemia, from esophageal speech to speech apraxia, from monastic silence to the family dynamics of children who maintain silence at school, from mutism after cerebral commissurotomy to muteness of the famous "wild child" of Aveyron. Lebrun's general approach is to provide vignettes illustrating each subject under discussion. Here the book is at its lucid best. Vignettes include not only generous summaries of case reports from the clinical literature but also illuminating examples from art, classic and modern literature, mythology, the Bible, and anthropology. Even etymology and slang expression find their way into Lebrun's eclectic treatise.

Mutism is more descriptive than explanatory, and some neurologists will look askance at the treatment of certain material. How, for example, are eating, toileting, copulating, and speaking—the four "primary modes of interaction with the environment" (p 45)—alike? Each of these, according to Lebrun in a discussion of functional mutism dynamics, "help[s] the individual outgrow an initial state of egocentrism and adapt to social life" (p 46). And what is a biologically oriented neuroscientist to conclude when words are metaphorically likened to sperm? Cursory explanations of organic causes of mutism are also disappointing in their pathophysiologic and anatomic simplicity.

Is *Mutism* an essential reference for the neurologist's personal library? I think not. However, *Mutism* is an enjoyable survey that provides a broad, well-referenced introduction to multifaceted aspects of speechlessness; it is on this basis that I recommend the book.

VICTOR W. HENDERSON, MD
Los Angeles, Calif

Trends in Neuroimmunology, edited by M. G. Marrosu, C. Cianchetti, and B. Tavolato, 169 pp, $50, New York, NY: Plenum Press, 1990.

This book represents the proceedings of the International Symposium on Trends in Neuroimmunology, Cagliari, Italy, in 1988. Based on this book, the symposium was excellent and would have been well worth attending. The authors of chapters are a distinguished international group of neuroimmunologists, mostly from Italy and other parts of Europe.

The book is organized into chapters on four broad areas representing current aspects of intense interest in neuroimmunology—humoral immunity, cellular immunity, immune functions of glia, and central nervous system immune diseases. Chapters describing work in human and animal systems are intermingled in a mutually reinforcing and provocative manner. Most of the chapters are original research reports, but two are review articles.

Several of the chapters describing original research reports are excellent, state-of-the-art accounts, some of which have subsequently either partially or completely appeared in print in refereed journals. These include chapters on antioligodendrocyte autoreactive T cells, human fetal brain cultures, and immunologic parameters and therapies in an impressive number of patients with subacute sclerosing panencephalitis. The chapter describing a negative search for human T-cell lymphotropic virus type I in patients with multiple sclerosis using polymerase chain reaction techniques is excellent, provides guidelines for others doing similar work, and has not appeared in any form elsewhere. Other chapters, however, on cerebrospinal fluid findings in patients infected with human immunodeficiency virus type 1 or in patients with MS discuss old techniques and confirm well-established concepts in Italian populations, or rework topics such as central nervous system IgG synthesis or B-cell responses in multiple sclerosis. The two review chapters on cerebrospinal fluid cytokines and on cellular immunity in slow viral infections are well written and referenced and provide interesting speculations.

The book would have been strengthened by having a review article in each broad subject area. Additionally, a question-and-answer or discussion section at the end of each chapter would have given the flavor of the discussions and interactions that took place at the symposium and that were enthusiastically referred to in the editors' introduction.

This book would hold much interest for those engaged in neuroimmunology research, but it is not comprehensive in its coverage of neuroimmunology. With the exception of the two review chapters, it is too specialized and would not hold great interest to a more general neurologic or medical audience.

DAVID H. MATTSON, MD, PHD
Rochester, NY

Neurologic Clinics, edited by William H. Theodore, 197 pp, with illus, $33, Philadelphia, Pa: WB Saunders Co, 1990.

Clinical Neuropharmacology represents the February 1990 issue of *Neurologic Clinics.* As with most issues in this series, only selected topics are chosen for review. The volume is not appropriate, therefore, for someone looking for a broad overview of clinical neuropharmacology. Eight chapters are included. The first two, "Basic Principles of Clinical Pharmacology" and "Clinical Trials," provide very good introductory material. The remainder of the chapters address specific neurologic disorders, including Parkinson's disease, hyperkinetic movement disorders, autonomic dysfunction, immune-related neuromuscular diseases, multiple sclerosis, head and face pain, sleep disorders, ischemic cerebrovascular disease, and epilepsy. Most chapters are clinically oriented, providing excellent and timely reviews of current approaches to therapy. The chapter on sleep disorders was disappointing in that it included only a very restricted discussion of sleep problems associated with Alzheimer's disease. This book is recommended for practicing neurologists, residents in training, and those interested in the specific topics covered.

Roger Kurlan, MD
Rochester, NY

Vascular Brain Stem Diseases, edited by B. Hofferberth, G. G. Brune, G. Sitzer, H.-D. Weger, with illus, $53.50, New York, NY, S Karger AG, 1990.

This book provides a systematic and comprehensive review of brain-stem vascular diseases. It is divided into four sections—structural and functional basis, epidemiology and clinical aspects, diagnostic tools, and therapy. The section on structural and functional basis reviews the anatomic organization of the brain stem and describes the vascular supply of the brain stem and arterial variations, based on the extensive experience of the author with autopsy material. In addition, an excellent review of the mechanisms of posterior circulation ischemia is provided. The final chapter in the section discusses the vestibulo-ocular system and provides detailed schematic diagrams that aid in understanding this complex topic. The next section focuses on epidemiologic and clinical aspects of vertebrobasilar vascular disease. The first chapter reviews epidemiologic aspects and is complete with illustrative tables and angiograms. The following two chapters complement each other with a discussion of signs and symptoms of "vertebrobasilar insufficiency" and brain-stem stroke syndromes.

A complete section on diagnostic and laboratory tools used in the evaluation of vertebrobasilar occlusive disease discusses the fine points of the neurotologic examination, posturography, electronystagmography, evoked responses, continuous-wave Doppler sonography, transcranial Doppler sonography, specialized hematologic testing, and radiologic methods.

The last section discusses treatment of vertebrobasilar occlusive disease, including medical and surgical options. It includes an overview of medical treatments, detailed information about the use of thrombolytic therapy in animals and humans, and a review of surgical procedures used for vertebrobasilar disease.

Overall, the book is well edited, but the writing style varies from chapter to chapter. Some typographical errors and several figures that are upside down are a minor problem. This volume, the result of an international workshop on the topic of vascular brain-stem diseases, would be recommended to neurology residents and neurologists who care for patients who have suffered a stroke.

José Biller, MD
Betsy B. Love, MD
Iowa City, Ia

Computational Neuroscience, edited by Eric L. Schwartz, 441 pp, with illus, $45, Cambridge, Mass, Massachusetts Institute of Technology Press, 1990.

This book is a collection of papers presented at a 1987 meeting that was, at least, partly intended to "define the field." It gathers papers from many of the most important contributors to computation neuroscience. Each author has written a chapter on some aspect of that author's work. Thus, this book is not intended as an introductory text. What it does provide, however, is a carefully written and well-edited presentation of many of the issues in computational neuroscience. It is particularly valuable because most chapters have been written from a broader perspective than one will find in the original literature. The chapters are grouped by the level of their approach (eg, synapse, network, neural map, or system). The book's structure is intentionally wide ranging and captures the diversity of the field. It might be fair to say that about the only sure unifying theme in *Computational Neuroscience* is its strong predisposition to describe the workings of the brain in quantitatively computable or mathematical terms. To most scientists there is a special appeal in mathematical models. This is particularly so when the mathematics is simple. However, even difficult models retain the appeal of explicitness.

Perhaps the most interesting dynamic in the field, and one that surfaces often in this book, is between the laboratory neuroscientists and the computer modeler. The modelers naturally want to produce "interesting" behavior from their models and are often willing to use simple approximations to neurons and synapses, ignoring a great deal of detail in the pursuit of greater computational realizability and simplicity of interpretation. Neuroscientists, just as naturally, insist that those neuroscientific details, wrested from the laboratories with such effort, should be included. In fact, many of the authors in this book are both laboratory scientists and computer modelers. Chapters by Gordon Shepard and Christof Koch are particularly insistent that the neuroscientific details are not yet well incorporated into most computational models.

Overall, this is a valuable volume to own, particularly so in a field as scattered about in the original literature as this. The articles are of very high quality and are faithful to their mission to be both computational and neuroscientific.

Letters to the Editor

Letters to the editor should be submitted as an original and two duplicates. They should be typewritten double-spaced on plain bond paper; they will be subject to editing. If they are prepared on a word processor, do not justify the right margin. A copyright transmittal letter signed by all authors must accompany this (see "Instructions for Authors").

Seizures Following Carotid Endarterectomy

To the Editor. I read the article by Kieburtz et al[1] entitled "Seizures Following Carotid Endarterectomy" with interest, and find it to be a surprising addition to the neurologic literature. There is no doubt that many patients have seizures following carotid endarterectomy (CEA). What one might doubt is the speculation that seizures following CEA may be attributed to "cerebral hyperperfusion, cerebral embolization, or both" as suggested by Kieburtz and colleagues.[1] In looking through their experience of 650 CEAs from 1981 through 1987, they found seizures occurring in eight patients, just more than 1%. Olsen et al[2] reviewed "Epilepsy After Stroke" and found a 9% incidence of recurrent seizures in a prospective series of 77 consecutive stroke patients. Other studies of epilepsy following stroke were cited: 5% by Aring and Merritt,[3] 6% by Richardson and Dodge,[4] 8% by Louis and McDowell,[5] 6% by Marquardsen,[6] and 7% by Fentz.[7] It is, therefore, not surprising that patients undergoing CEA, many having had clinical or subclinical cerebrovascular accidents, should occasionally manifest seizures. That altered regional hemodynamics could trigger a seizure in a patient with cortical damage is a reasonable, if unproven, hypothesis. To be avoided is a suggestion that embolism or hyperperfusion per se are primarily responsible.

Reigel et al,[8] whose article is cited eight times by Kieburtz et al,[1] describe "cerebral hyperperfusion syndrome" in 10 patients, nine of whom had "clinical seizures"; the 10th had evidence of "subclinical seizures," ie, periodic lateralized epileptiform discharges (PLEDs) on electroencephalogram. Although descriptions of "seizures" are lacking, all 10 electroencephalograms are described as having shown "PLEDs." It is notable that PLEDs indicate an acute alteration of cerebral function and that although PLEDs can be seen in seizure patients, they are far from specific to that disorder. In fact, the most common cause in an elderly person is probably stroke.

If a significant number of seizures occurred during extracranial-intracranial bypass, that is, convulsions in patients without a clear embolic source for cortical infarction, hyperperfusion might be more reasonably implicated. That a small number of patients with stroke have seizures is well established; it is remarkable that so few occur in patients with CEA: 0.4% in the Mayo Clinic study[8] and 1% in the article by Kieburtz and coworkers.[1] Reigel et al[8] and Kieburtz et al[1] have added to our understanding of seizures, perhaps, in showing us that in a selected group of high-risk patients, seizures may occur less often than expected. I would not go so far as to suggest that the paucity of seizures in this group supports the notion, growing in popularity in recent years, that many of these patients do not have a disease that is benefited by surgery. The latter issue should be resolved as the results of ongoing controlled trials of carotid endarterectomy become available.

In Reply.—In his letter, Sinoff asserts that seizures following carotid endarterectomy (CEA) occurred less frequently than expected in our study population. To substantiate his assertion he provides several references for the incidence of seizures following *stroke.* We suggest that not all patients having a CEA also have a stroke. A generous estimate of the incidence of stroke following CEA at our institution is 5%, based on prior reports from our institution and others.[1,2] Using this estimate for the incidence of stroke in patients with CEA, and using the incidence figures for seizure following stroke provided by Sinoff, 2.25 cases of seizures due to stroke following CEA would have been expected in our study population. This falls outside the 95% confidence interval for the observed number of eight cases of seizures following CEA, based on the binomial distribution. Therefore, we actually reported that seizures following CEA occurred *more* frequently than expected, if stroke were the sole cause of the seizures. We reiterate our previous statement that although there are several hypotheses regarding the mechanism of seizures following CEA (including embolization and hyperperfusion), the exact pathogenesis remains unclear.

Convergence Nystagmus Associated With Arnold-Chiari Malformation

To the Editor.—In the March 1990 issue of the Archives, Mossman et al[1] detailed the neuro-ophthalmologic findings of a convergence nystagmus associated with Arnold-Chiari malformation type I in a 17-year-old boy. This type of nystagmus, occurring usually with lesions of the pretectal region,[2,3] appeared only during neck movements and Valsalva's maneuver, and was absent in the primary position of gaze with the head in the neutral position. We congratulate the authors for the accuracy of the electro-oculographic and magnetic resonance imaging studies of the case, and we agree with their brilliant hypothesis that, even in the absence of an overt pretectal lesion, the appearance of convergence nystagmus might be explained on the basis of transient dysfunction of periaqueductal structures provoked by mechanical and/or hydrodynamic mechanisms occurring during neck movements and Valsalva's maneuver, ie, distortion of the aqueductal region and transient rise of cerebrospinal fluid pressure within the ventricular system. Our disagreement with the authors concerns, instead, the statement that the case studied showed the features of Arnold-Chiari malformation type I. Besides the depression of the lower poles of cerebellar tonsils up to C-2 and a moderate hydrocephalus involving the lateral and third ventricles, magnetic resonance imaging showed that the anterior recesses of the third ventricle, as well as of the fourth ventricle, were slightly distended, the brain stem was depressed, and the medulla appeared to be elongated with its anterior surface impressed by the tissues overlying the odontoid process. Furthermore, there was kinking of the cervicomedullary junction and a large syrinx extending from the level of C-3 to D-10. The hindbrain malformations revealed by magnetic resonance imaging do not resemble at all the anatomic features of type I Arnold-Chiari malformation. According to the original description of Chiari[4] and recent quantitative approaches to Chiari malformations with magnetic resonance imaging,[5] as well as several references quoted in the literature,[6-12] Arnold-Chiari malformation type I corresponds simply to a displacement, more or less pronounced, of the cerebellar tonsils into the upper cervical canal without caudal displacement of the medulla. Furthermore, although clinical presentation of Arnold-Chiari malformation type I often suggests a cerebellar and/or an upper cervical cord lesion, in some cases the malformation is asymptomatic and the diagnosis is occasional. We believe that to diagnose Arnold-Chiari malformation type I, any hindbrain anomaly different from Chiari's original definition is misleading.

In Reply.—We are pleased that your correspondents agree with our description of the abnormalities and of the implications drawn from them and that disagreement is confirmed to our categorization of the patient as a Chiari type I malformation.

It is true that in Chiari's original description of the type I malformation only the cerebellar tonsils are displaced inferiorly, and it is therefore historically correct to include only cases of pure cerebellar ectopia in the Chiari type I category. However, one is then left with a large majority of patients in whom depression of the cerebellar tonsils is associated with varying degrees of depression of the medulla. In some of these cases there is a typical cervicomedullary kink at the level of the depressed dorsal column nuclei. Syrinx formation is commonly present. If these are not to be classified as Chiari type I malformations, what is the correct terminology? They certainly do not fit into the category of Chiari type II malformations in which the fundamental abnormality is incomplete formation of the pontine flexure. In Chiari type II malformations there is elongation of the pons and medulla and malformation of the cerebellar vermis, the hindbrain extending down into the cervical canal with the nodulus at the leading edge of the depressed cerebellum. This malformation also is associated with syringomyelia or hydromyelia, and almost always with dysraphism, usually meningomyelocele.

It is evident that in depression of the medulla, in addition to the tonsils, it is not always a malformation, but a deformation secondary to compression of the posterior fossa contents. This may occur, for example, in severe craniostenosis or in the type of basilar invagination with convexobasia associated with osteogenesis imperfecta, and it is likely that many other cases termed Chiari type I malformations are in truth acquired deformities. However, even if cases with medullary in addition to tonsillar depression do not strictly conform to Chiari's original description, we believe that they are fundamentally different from the type II malformation and can reasonably be considered as an extension of type I. It would be facetious and inaccurate to refer to them as Chiari type 1.5, but to do so would draw attention to the dilemma caused by the eponymous terminology.

PERMAX®
pergolide mesylate

An added dimension
in the treatment of
Parkinson's disease

An adjunct to levodopa/carbidopa in the management of patients with Parkinson's disease

- The first dopamine agonist indicated for Parkinson's disease with activity at both D_1 and D_2 receptors
- 10 to 1,000 times more potent than bromocriptine on a milligram-per-milligram basis
- Improves patients' functioning in activities of daily living, relieves signs and symptoms, and reduces "off" time
- May allow a significant reduction in levodopa dosage
- Most common adverse events were dyskinesia, nausea, dizziness, and hallucinations
- Hypotension may occur, especially early in the course of therapy
- Stepwise titration without regard to meals
- Available in 0.05-mg, 0.25-mg, and 1-mg scored tablets

Permax performs

Permax®

pergolide mesylate

Brief Summary. Consult the package insert for complete prescribing information.

Indications and Usage: Permax is indicated as adjunctive treatment to levodopa/carbidopa in the management of the signs and symptoms of Parkinson's disease.

Evidence to support the efficacy of pergolide mesylate as an antiparkinsonian adjunct was obtained in a multicenter study enrolling 376 patients with mild to moderate Parkinson's disease who were intolerant to levodopa/carbidopa as manifested by moderate to severe dyskinesia and/or on-off phenomena. On average, the sample of patients evaluated had been on levodopa/carbidopa for 3.9 years (range, two days to 16.8 years). The administration of pergolide mesylate permitted a 5% to 30% reduction in the daily dose of levodopa. On average, these patients treated with pergolide mesylate maintained an equivalent or better clinical status than they exhibited at baseline.

Contraindications: Pergolide mesylate is contraindicated in patients who are hypersensitive to this drug or other ergot derivatives.

Warnings: *Symptomatic Hypotension* —In clinical trials, approximately 10% of patients taking pergolide mesylate with levodopa vs 7% taking placebo with levodopa experienced symptomatic orthostatic and/or sustained hypotension, especially during initial treatment. With gradual dosage titration, tolerance to the hypotension usually develops. It is, therefore, important to warn patients of the risk, to begin therapy with low doses, and to increase the dosage in carefully adjusted increments over a period of three to four weeks.

Hallucinosis —In controlled trials, pergolide mesylate with levodopa caused hallucinosis in about 14% of patients as opposed to 3% taking placebo with levodopa. This was of sufficient severity to cause discontinuation of treatment in about 3% of those enrolled; tolerance to this untoward effect was not observed.

Fatalities —In the placebo-controlled trial, two of 187 patients treated with placebo died as compared with one of 189 patients treated with pergolide mesylate. Of the 2,299 patients treated with pergolide mesylate in premarketing studies evaluated as of October 1988, 143 died while on the drug or shortly after discontinuing the drug. The patient population under evaluation was elderly, ill, and at high risk for death. It seems unlikely that pergolide mesylate played any role in these deaths, but the possibility that pergolide shortens survival of patients cannot be excluded with absolute certainty.

In particular, a case-by-case review of the clinical course of the patients who died failed to disclose any unique set of signs, symptoms, or laboratory results that would suggest that treatment with pergolide caused their deaths. Sixty-eight percent (68%) of the patients who died were 65 years of age or over. No death (other than a suicide) occurred within the first month of treatment; most of the patients who died had been on pergolide for years. A relative frequency of the causes of death by organ system are: pulmonary failure/pneumonia, 35%; cardiovascular, 30%; cancer, 11%; unknown, 8.4%; infection, 3.5%; extrapyramidal syndrome, 3.5%; stroke, 2.1%; dysphagia, 2.1%; injury, 1.4%; suicide, 1.4%; dehydration, 0.7%; glomerulonephritis, 0.7%.

Precautions: *General* —Caution should be exercised when administering pergolide mesylate to patients prone to cardiac dysrhythmias.

In a study comparing pergolide mesylate and placebo, patients taking pergolide mesylate were found to have significantly more episodes of atrial premature contractions (APCs) and sinus tachycardia.

The use of pergolide mesylate in patients on levodopa may cause and/or exacerbate preexisting states of confusion and hallucinations (*see* Warnings). Also, the abrupt discontinuation of pergolide mesylate in patients receiving it chronically as an adjunct to levodopa may precipitate the onset of hallucinations and confusion; these may occur within a span of several days. Discontinuation of pergolide should be undertaken gradually whenever possible, even if the patient is to remain on levodopa.

The administration of pergolide mesylate to patients receiving levodopa may cause and/or exacerbate preexisting dyskinesia.

Information for Patients —Patients and their families should be informed of the common adverse consequences of the use of pergolide mesylate (*see* Adverse Reactions) and the risk of hypotension (*see* Warnings).

Patients should be advised to notify their physician if they become pregnant or intend to become pregnant during therapy.

Patients should be advised to notify their physician if they are breast feeding an infant.

Laboratory Tests —No specific laboratory tests are deemed essential for the management of patients on Permax. Periodic routine evaluation of all patients, however, is appropriate.

Drug Interactions —Dopamine antagonists, such as the neuroleptics (phenothiazines, butyrophenones, thioxanthines) or metoclopramide, ordinarily should not be administered concurrently with Permax (a dopamine agonist); these agents may diminish the effectiveness of Permax.

Because pergolide mesylate is approximately 90% associated with plasma proteins, caution should be exercised if pergolide mesylate is coadministered with other drugs known to affect protein binding.

Carcinogenesis, Mutagenesis, and Impairment of Fertility —A two-year carcinogenicity study was conducted in mice using dietary levels of pergolide mesylate equivalent to oral doses of 0.6, 3.7, and 36.4 mg/kg/day in males and 0.6, 4.4, and 40.8 mg/kg/day in females. A two-year study in rats was conducted using dietary levels equivalent to oral doses of 0.04, 0.18, and 0.88 mg/kg/day in males and 0.05, 0.28, and 1.42 mg/kg/day in females. The highest doses tested in the mice and rats were approximately 340 and 12 times the maximum human oral dose administered in controlled clinical trials (6 mg/day equivalent to 0.12 mg/kg/day).

A low incidence of uterine neoplasms occurred in both rats and mice. Endometrial adenomas and carcinomas were observed in rats. Endometrial sarcomas were observed in mice. The occurrence of these neoplasms is probably attributable to the high estrogen/progesterone ratio which would occur in rodents as a result of the prolactin-inhibiting action of pergolide mesylate. The endocrine mechanisms believed to be involved in the rodents are not present in humans. However, even though there is no known correlation between uterine malignancies occurring in pergolide-treated rodents and human risk, there are no human data to substantiate this conclusion.

Pergolide mesylate was evaluated for mutagenic potential in a battery of tests that included an Ames bacterial mutation assay, a DNA repair assay in cultured rat hepatocytes, a point-mutation assay in cultured L5178Y cells, and a determination of chromosome alteration in bone marrow cells of Chinese hamsters. A weak mutagenic response was noted in the in vitro mammalian cell-point-mutation assay using L5178Y cells only after metabolic activation with rat liver microsomes. No mutagenic effects were obtained in the two other in vitro assays and in the in vivo assay. The relevance of these findings to humans is unknown.

A fertility study in male and female mice showed that fertility was maintained at 0.6 and 1.7 mg/kg/day but decreased at 5.6 mg/kg/day. Prolactin has been reported to be involved in stimulating and maintaining progesterone levels required for implantation in mice and, therefore, the impaired fertility at high dose may occur because of depressed prolactin levels.

Usage in Pregnancy—Pregnancy Category B —Reproduction studies were conducted in mice at doses of 5, 16, and 45 mg/kg/day and in rabbits at doses of 2, 6, and 16 mg/kg/day. The highest doses tested in mice and rabbits were 375 and 133 times the 6 mg/day maximum human dose administered in controlled clinical trials. In these studies, there was no evidence of harm to the fetus due to pergolide mesylate.

There are, however, no adequate and well-controlled studies in pregnant women. Among women who received pergolide mesylate for endocrine disorders in premarketing studies, there were 33 pregnancies that resulted in healthy babies and four pregnancies that resulted in congenital abnormalities (two major, two minor); a causal relationship has not been established. Because human data are limited and because animal reproduction studies are not always predictive of human response, this drug should be used during pregnancy only if clearly needed.

Nursing Mothers —It is not known whether this drug is excreted in human milk. The pharmacologic action of pergolide mesylate suggests that it may interfere with lactation. Because many drugs are excreted in human milk and because of the potential for serious adverse reactions to pergolide mesylate in nursing infants, a decision should be made whether to discontinue nursing or to discontinue the drug, taking into account the importance of the drug to the mother.

Pediatric Use —Safety and effectiveness in children have not been established.

Adverse Reactions: *Commonly Observed* —In premarketing clinical trials, the most commonly observed adverse events associated with use of pergolide mesylate which were not seen at an equivalent incidence among placebo-treated patients were: nervous system complaints, including dyskinesia, hallucinations, somnolence, insomnia; digestive complaints, including nausea, constipation, diarrhea, dyspepsia; and respiratory system complaints, including rhinitis.

Associated With Discontinuation of Treatment —Twenty-seven percent (27%) of approximately 1,200 patients receiving pergolide mesylate for treatment of Parkinson's disease in premarketing clinical trials in the US and Canada discontinued treatment due to adverse events. The events most commonly causing discontinuation were related to the nervous system (15.5%), primarily hallucinations (7.8%) and confusion (1.8%).

Fatalities –*See* Warnings.

Incidence in Controlled Clinical Trials —The table that follows enumerates adverse events that occurred at a frequency of 1% or more among patients taking pergolide mesylate who participated in the premarketing controlled clinical trials comparing pergolide mesylate with placebo. In a double-blind, controlled study of six months' duration, patients with Parkinson's disease were continued on levodopa/carbidopa and were randomly assigned to receive either pergolide mesylate or placebo as additional therapy.

The prescriber should be aware that these figures cannot be used to predict the incidence of side effects in the course of usual medical practice where patient characteristics and other factors differ from those which prevailed in the clinical trials. Similarly, the cited frequencies cannot be compared with figures obtained from other clinical investigations involving different treatments, uses, and investigators. The cited figures, however, do provide the prescribing physician with some basis for estimating the relative contribution of drug and nondrug factors to the side-effect incidence rate in the population studied.

Incidence of Treatment-Emergent Adverse Experiences in the Placebo-Controlled Clinical Trial

*Events reported by at least 1% of patients receiving pergolide mesylate are included.

Events Observed During the Premarketing Evaluation of Permax —This section reports event frequencies evaluated as of October 1988 for adverse events ocurring in a group of approximately 1,800 patients who took multiple doses of pergolide mesylate. The conditions and duration of exposure to pergolide mesylate varied greatly, involving well-controlled studies as well as experience in open and uncontrolled clinical settings. In the absence of appropriate controls in some of the studies, a causal relationship between these events and treatment with pergolide mesylate cannot be determined.

The following enumeration by organ system describes events in terms of their relative frequency of reporting in the data base. Events of major clinical importance are also described in the Warnings and Precautions sections.

The following definitions of frequency are used: frequent adverse events are defined as those occurring in at least 1/100 patients; infrequent adverse events are those occurring in 1/100 to 1/1,000 patients; rare events are those occurring in fewer than 1/1,000 patients.

Body as a Whole —*Frequent:* headache, asthenia, accidental injury, abdominal pain, chest pain, back pain, flu syndrome, neck pain, fever; *Infrequent:* facial edema, chills, enlarged abdomen, malaise, neoplasm, hernia, pelvic pain, sepsis, cellulitis, moniliasis, abscess, jaw pain, hypothermia; *Rare:* acute abdominal syndrome, LE syndrome

Cardiovascular System —*Frequent:* postural hypotension, syncope, hypertension, palpitations, vasodilatations, congestive heart failure; *Infrequent:* myocardial infarction, tachycardia, heart arrest, abnormal electrocardiogram, angina pectoris, thrombophlebitis, bradycardia, ventricular extrasystoles, cerebrovascular accident, ventricular tachycardia, cerebral ischemia, atrial fibrillation, varicose vein, pulmonary embolus, AV block, shock; *Rare:* vasculitis, pulmonary hypertension, pericarditis, migraine, heart block, cerebral hemorrhage

Digestive System —*Frequent:* nausea, vomiting, dyspepsia, diarrhea, constipation, dry mouth, dysphagia; *Infrequent:* flatulence, abnormal liver function tests, increased appetite, salivary gland enlargement, thirst, gastroenteritis, gastritis, periodontal abscess, intestinal obstruction, nausea and vomiting, gingivitis, esophagitis, cholelithiasis, tooth caries, hepatitis, stomach ulcer, melena, hepatomegaly, hematemesis, eructation; *Rare:* sialadenitis, peptic ulcer, pancreatitis, jaundice, glossitis, fecal incontinence, duodenitis, colitis, cholecystitis, aphthous stomatitis, esophageal ulcer.

Endocrine System —*Infrequent:* hypothyroidism, adenoma, diabetes mellitus, ADH inappropriate; *Rare:* endocrine disorder, thyroid adenoma

Hemic and Lymphatic System —*Frequent:* anemia; *Infrequent:* leukopenia, lymphadenopathy, leukocytosis, thrombocytopenia, petechia, megaloblastic anemia, cyanosis; *Rare:* purpura, lymphocytosis, eosinophilia, thrombocythemia, acute lymphoblastic leukemia, polycythemia, splenomegaly

Metabolic and Nutritional System —*Frequent:* peripheral edema, weight loss, weight gain; *Infrequent:* dehydration, hypokalemia, hypoglycemia, iron deficiency anemia, hyperglycemia, gout, hypercholesteremia; *Rare:* electrolyte imbalance, cachexia, acidosis, hyperuricemia

Musculoskeletal System —*Frequent:* twitching, myalgia, arthralgia; *Infrequent:* bone pain, tenosynovitis, myositis, bone sarcoma, arthritis; *Rare:* osteoporosis, muscle atrophy, osteomyelitis

Nervous System —*Frequent:* dyskinesia, dizziness, hallucinations, confusion, somnolence, insomnia, dystonia, paresthesia, depression, anxiety, tremor, akinesia, extrapyramidal syndrome, abnormal gait, abnormal dreams, incoordination, psychosis, personality disorder, nervousness, choreoathetosis, amnesia, paranoid reaction, abnormal thinking; *Infrequent:* akathisia, neuropathy, neuralgia, hypertonia, delusion, convulsion, libido increased, euphoria, emotional lability, libido decreased, vertigo, myoclonus, coma, apathy, paralysis, neurosis, hyperkinesia, ataxia, acute brain syndrome, torticollis, meningitis, manic reaction, hypokinesia, hostility, agitation, hypotonia; *Rare:* stupor, neuritis, intracranial hypertension, hemiplegia, facial paralysis, brain edema, myelitis, hallucinations and confusion after abrupt discontinuation

Respiratory System —*Frequent:* rhinitis, dyspnea, pneumonia, pharyngitis, cough increased; *Infrequent:* epistaxis, hiccup, sinusitis, bronchitis, voice alteration, hemoptysis, asthma, lung edema, pleural effusion, laryngitis, emphysema, apnea, hyperventilation; *Rare:* pneumothorax, lung fibrosis, larynx edema, hypoxia, hypoventilation, hemothorax, carcinoma of lung

Skin and Appendages System —*Frequent:* sweating, rash; *Infrequent:* skin discoloration, pruritus, acne, skin ulcer, alopecia, dry skin, skin carcinoma, seborrhea, hirsutism, herpes simplex, eczema, fungal dermatitis, herpes zoster; *Rare:* vesiculobullous rash, subcutaneous nodule, skin nodule, skin benign neoplasm, lichenoid dermatitis

Special Senses System —*Frequent:* diplopia; *Infrequent:* otitis media, conjunctivitis, tinnitus, deafness, taste perversion, ear pain, eye pain, glaucoma, eye hemorrhage, photophobia, visual field defect; *Rare:* blindness, cataract, retinal detachment, retinal vascular disorder

Urogenital System —*Frequent:* urinary tract infection, urinary frequency, urinary incontinence, hematuria, dysmenorrhea; *Infrequent:* dysuria, breast pain, menorrhagia, impotence, cystitis, urinary retention, abortion, vaginal hemorrhage, vaginitis, priapism, kidney calculus, fibrocystic breast, lactation, uterine hemorrhage, urolithiasis, salpingitis, pyuria, metrorrhagia, menopause, kidney failure, breast carcinoma, cervical carcinoma; *Rare:* amenorrhea, bladder carcinoma, breast engorgement, epididymitis, hypogonadism, leukorrhea, nephrosis, pyelonephritis, urethral pain, uricaciduria, withdrawal bleeding

Results of Surgery for Extratemporal Partial Epilepsy That Began in Childhood

John Adler, MD; Giuseppe Erba, MD; Ken R. Winston, MD; Keasley Welch, MD; Cesare T. Lombroso, MD, PhD

• Thirty-five consecutive patients who underwent surgery for intractable extratemporal seizures originating in childhood are described. Candidates for surgery were selected on the basis of clinical criteria, neurodiagnostic imaging, and an electroencephalographic investigation that included the use of sphenoidal electrodes and long-term monitoring. Invasive preoperative monitoring was not used. Our results, with respect to the control of seizures and behavioral improvement, are comparable with series in which data from invasive recordings were used in the selection process. Sixty-three percent of the 35 patients (76.5% of those operated on after the introduction of long-term electroencephalographic monitoring) became either seizure free or experienced a reduction in their frequency of seizures by at least 75%. The favorable outcome in this group of patients strengthens the argument for early operation in children with intractable epilepsy, even when the seizure focus is outside the temporal lobe.

(*Arch Neurol.* 1991;48:133-140)

Surgery for seizures that began in childhood, and neurosurgery itself, was born on May 25, 1886. On that date, an innovative 29-year-old English surgeon nicknamed Archibald Allright, which is perhaps a clue to his skill and optimism, performed his first operation on the human brain and the first operation ever for epilepsy. The patient, referred by Hughlings Jackson, was a 22-year-old whose seizures began in childhood and occurred as frequently as 3000 per fortnight.[1,2] Although the patient was seizure free postoperatively, the follow-up was short by current standards—3 months at the time of the report. Professor Charcot, visiting from Paris, France, on hearing the presentation of this and two other cases, congratulated the surgeon, Victor Horsley, for having cured epilepsy by operation.[1] The core element of surgery for epilepsy, excision of the epileptogenic complex, has not changed from that date. What have changed and continue to change are our methods and rationale for selecting patients for surgery, the operative techniques, and our analysis of surgical results.

"Seizures are frightening, cause damage, and are a major contribution to social isolation,"[3] yet the traditional approach to epilepsy in children has tended toward nonoperative management, probably because seizures in some children, unlike those in adults, can be self-limiting.[4] As a result, children with recalcitrant seizure disorders who may profit from surgery often have this therapy delayed unnecessarily or withheld.[5-7] Even for patients who undergo this treatment, the selection process and the surgical techniques vary appreciably among medical centers,[8] and the optimal age for intervention remains uncertain.

Surgery in carefully selected children reduces or eliminates seizures and facilitates social adaptation[9,10]; however, nearly all published series of operations for epilepsy in the pediatric age group have been dominated by temporal lobectomies.[11-14] Because temporal lobectomy consistently yields more favorable results than other anatomically defined cortical resections,[15-17] results from the reported series are not representative of results for the more challenging extratemporal locations. This report will focus on our experience with the surgical management of chronic epilepsy due to extratemporal cortical seizure foci identified by noninvasive means, ie, without preoperative dural or depth recordings.

PATIENTS AND METHODS

All patients who underwent surgery at The Children's Hospital, Boston, Mass, between January 1972 and August 1987 for chronic, extratemporal, partial epilepsy originating in childhood are the basis of this report. Patients with hemispheral abnormalities who underwent extensive cortical resections are included; those who had temporal lobectomy or hemicorticectomy are excluded. We placed no limit on age at the time of surgery but required that the epilepsy begin within the pediatric age group, ie, before 16 years of age. Except for children younger than 2 years of age, we excluded those whose epilepsy had been present for less than 2 years. Although not all patients were children at the time of surgery, the median age at operation was 15 years. There was no apparent change in the pattern of referral of our patients during the accrual of this series, and our series is relatively uniform with respect to the neurologists and neurosurgeons involved, the operative techniques employed, and the fact that implanted electrodes (depth, epidural, or subdural) were not used. Consequently, we believe that this series is representative of the contemporary experience with intractable extratemporal partial epilepsy in children who are appropriate candidates for surgical intervention.

*Treatment administered to 35 consecutive patients who underwent surgery for extratemporal partial epilepsy that began in childhood.

†Receiving or not receiving medication.

All patients had received multiple trials of anticonvulsant medications and were referred for management of recalcitrant seizure disorders. Each patient was restudied at our institution with extensive electroencephalography (EEG), which included provocative and localizing tests (intravenous thiopental,[18] diazepam,[19] or methohexital[20]) in most patients. Nasopharyngeal electrodes were placed for basal EEG recording after 1972; sphenoidal electrodes, as well as other special electrodes, were used after 1979. Long-term monitoring for the purpose of recording multiple seizures became available in 1981. No patients in this series underwent invasive preoperative investigations, such as implanting dural strip electrodes or having depth electrodes implanted on a long-term basis.

All patients underwent the following intensive neuroradiologic testing: pneumoencephalography before 1974, computed tomography (CT) after 1974, and, more recently, magnetic resonance imaging (MRI). An attempt to identify discrete radiographic abnormalities was made in each case. The radiographs of all patients whose studies were considered to be negative at the time of surgery were reviewed again at the time of this investigation. Neuropsychological testing[21-23] was administered before and after surgery in all patients, including the very young children. Intracarotid injection of amobarbital sodium[24] for lateralization of speech and for testing of memory[22] was performed preoperatively in patients in whom this information was deemed useful and who were sufficiently cooperative.

Surgery was recommended on an individual basis, not according to a fixed protocol. General anesthesia was employed in all cases in this series. After opening the dura and exposing the surface of the brain, electrocorticography was performed with a 16-channel instrument (model 8, Grass Instruments, Quincy, Mass) both to confirm the localization of abnormalities identified preoperatively on noninvasive EEGs and to guide the extent of surgical resection. During electrocorticography, methohexital was often injected intravenously to precipitate or enhance abnormalities previously seen on EEG.[20] Cortical stimulation was not used. In general, standard surgical techniques were employed. When a neoplasm was encountered, the operative technique was modified as needed in an attempt to achieve total resection. In general, the extent of the resection in patients with neoplasia was guided by the surgeon's ability to identify abnormal tissue. Cortex overlying tumor was resected and, if electrocorticography then revealed persistent seizure foci in surrounding cortex, the electrophysiologically abnormal tissue was then also removed (if the area was considered safe for resection).

All operative specimens were processed in routine fashion by the department of pathology (neuropathology) of The Children's Hospital, and a histopathologic analysis was obtained in all cases.

Patients received anticonvulsant medications in the immediate postoperative period; these medications were reduced when warranted, based on clinical features and findings on EEG. When the epilepsy remained poorly controlled, a second operation was performed.

Postoperative follow-up was primarily at The Children's Hospital. All available information on the control of seizures, including observations by patients' families and reports from the referring physicians, was collected for each patient. The following scale was used to quantitate the effectiveness of surgery: 0, no definite improvement; 1, slight improvement (approximately 25%); 2, moderate improvement (approximately 50%); 3, near complete control with only rare seizures (at least 75% improvement); and 4, total seizure control (with or without medications). This score reflected the frequency of seizures throughout the postoperative period (after the last operation in those patients having two operations). Convulsive attacks in the immediate postoperative period and those clearly related to withdrawal of anticonvulsant therapy were not considered. For patients with several years' follow-up, the grading reflected the frequency of seizures in the few years immediately preceding this survey. When a patient had two seizure patterns and a different response to surgery for each, the average change was recorded. Because of the inherent error in quantitating small improvements in seizure control and because small improvements may not be very beneficial to the patient, we have considered "significant improvement" to be a reduction of at least 75% (ie, scores 3 and 4).

Postoperative performance, incorporating both social functioning and the results of neuropsychological testing, was evaluated, and each patient was given a performance rating. The purpose of the performance rating was to assess changes in intellectual and social behavior that were not directly dependent on the control of seizures. For example, a patient who was a good student despite frequent seizures and who remained a good student after surgery, albeit without seizures, was classified as having no change in performance. Changes in performance were usually best documented in the results of neuropsychological testing, but sometimes change was most apparent in reports from school, employer, or parents. Using the preoperative condition as a baseline, the following categories were used to rate performance: W, worse; NC, no change; M, improved but with new and unexpected neurological deficits; and I, improved.

RESULTS

Thirty-five patients who underwent 39 operations for epilepsy form the basis of this report. The characteristics of the whole group and the aggregate results of surgery are presented in Table 1. Sixty-three percent of patients became either seizure free or experienced a significant reduction in the frequency of seizures. No patient's seizure disorder was made worse by that patient's undergoing an operation, and only four patients (11%) failed to have some improvement in control of seizures.

The first 18 patients (operated on before January 1, 1980) had a mean postoperative seizure grade of 2.2, and 50% of these patients experienced a significant improvement in control of seizures (score 3 or 4); the subsequent 17 patients had a mean postoperative seizure grade of 2.9 and 76% had a significant improvement in control of seizures. The postoperative performance rating, however, was approximately the same in the two periods—39% of the first 18 patients were improved vs 47% of the latter. Overall, the performance rating after surgery was improved in 15 patients (43%), although two of these had new neurologic deficits. Two patients had a worse postoperative performance rating: one had chronic encephalitis and another had a pre-existing contralateral frontal injury from radiation therapy; behavioral deficits developed following removal of an extensive region of porencephaly and cicatrix due to tumor removal years before.

Outcome by Anatomic Location

The general characteristics of the patients, when grouped by location of cortical resection and the results of surgical treatment, are presented in Tables 2 and 3.

Table 2.—General Characteristics and Results of Surgery by Location of Cortical Resection

‡May include excision of temporal lobe with extratemporal cortex.

Frontal Lobe.—Control of seizures was significantly improved in nine of 14 patients who underwent frontal resection (64%). Eight patients (57%) became seizure free; three of the nine had an improved performance rating; and one was worse (frontal syndrome). The one patient with no apparent benefit (grade 0) from frontal corticectomy had a large tumor that could not be totally removed. Four patients had a postoperative seizure grade of 1 or 2; two of these underwent an operation on the basis of interictal EEG foci without corresponding abnormalities on neurodiagnostic imaging. The third patient had a focal abnormality on CT but no clear focus on EEG. The fourth patient had nonspecific pathologic lesions and was operated on while in status epilepticus (epilepsia partialis continua). None of the five patients without significant improvement had preoperative long-term monitoring of ictal events.

Parietal Lobe.—All three patients had excellent control of seizures after surgery and two had improved performance ratings.

Occipital Lobe.—Four of five patients (five different pathologic findings) had significantly improved control of seizures. The one who did not improve had nonspecific pathologic findings and presented with epilepsia partialis continua. The performance rating improved in three patients and was unchanged in two.

Multilobar.—Six (46%) of 13 patients had postoperative seizure grades of 3 or 4 and six patients had an improved performance rating after surgery. Five of seven patients with little or no improvement in seizure control had incomplete removal of their lesions. The one patient with a worse postoperative performance had relentlessly progressive chronic encephalitis.

Outcome by Pathologic Abnormality

All surgical specimens contained histopathologic abnormalities (Tables 3 through 5 and the Figure). The 35 cases can be grouped into seven categories on the basis of gross and histologic features.

Tumor.—Eleven patients (31%) had intractable epilepsy attributable to neoplasia; the anatomic distribution of these tumors is shown in Table 6, and the distribution of histologic types is displayed in the Figure. Seven patients (64%) had improved seizure control, four (36%) of whom became seizure free. Control of seizures was not related to type of tumor but rather to the extent of removal and to the degree of malignancy. The two patients in whom postoperative improvement in seizures was absent (score, 0) had large and incompletely resected tumors. Their performance rating is summarized in Tables 3 and 5.

Atrophic and Cicatricial Lesions.—This pathologic category accounted for five patients (14% of the total), and the control of seizures was significantly improved in four of them (80%). Four of the five had porencephaly; three of

*W indicates worse; NC, no change; M, improved with new neurologic deficit; and I, improved.

the five had an extensive multilobar resection and one had an occipital lobectomy. Patients with atrophic lesions had a high proportion of postsurgical improvement in performance (four [80%] of five improved). None of the patients became seizure free, but four of five had at least a 75% reduction in seizures and also a significant improvement in performance.

Vascular Malformations.—All three patients became seizure free; performance was improved in two patients and one patient experienced no change. None had experienced a clinically apparent hemorrhage.

Cortical Malformation—Hamartoma and Tuberous Sclerosis.—Five of six patients had a significantly improved seizure score, and three of these patients are seizure free. Three had an improved performance rating and the remainder were unchanged.

Chronic Encephalitis.—One of two patients presented with epilepsia partialis continua and postoperatively experienced a relentless progression, sufficient to necessitate institutionalization; the other patient's condition remained stable but the epilepsy was not improved. Two other patients (ie, two not classified as having chronic encephalitis) presented with epilepsia partialis continua, and their surgical specimens had gliosis and perivascular cuffing but not neuronophagia or glial nodules. Although these abnormalities could represent the residua of encephalitis, these two patients were included in the nonspecific group.

Nonspecific Abnormality.—Two (29%) of seven patients with this pathologic diagnosis had significantly improved seizure control. One patient had an improved performance rating, six patients had ratings that were unchanged, and no patient's ratings were worse. Gliosis was the most common nonspecific histologic feature; it was present in seven cases. Gliosis was associated with neuronal loss in two patients and calcification in one. Three of these patients had evidence of focal atrophy on CT, and in one bilateral dilatation of the temporal horns was noted. No apparent relationship between postoperative control of seizures and either the radiographic appearance or the histologic findings in these patients was seen.

Epilepsia Partialis Continua

Three patients had epilepsia partialis continua for an average of 2.3 years before surgery. Cortical resections were in the occipital, frontal, and frontoparietal regions. One patient had the typical histologic features of encephalitis; the other two patients had nonspecific histologic changes. After the operation, none of these patients had any significant change in the character or frequency of the epilepsia partialis continua.

Table 6.—Anatomic Distribution of 11 Neoplasms*

Site	N (%)
Frontal lobe	6 (54)
Occipital lobe	1 (9)
Frontoparietal region	1
Parieto-occipital region	2 (36)
Parietotemporal region	1
Total	**11 (99)**

*Sample is from 35 patients who had undergone surgery for chronic extratemporal partial epilepsy that began in childhood. Sum of percentages is less than 100 due to rounding.

Anticonvulsant Therapies

At the close of this study, five patients (14%) were receiving no anticonvulsants; clearly, these patients had good results from surgery and were seizure free. Twelve patients (34%) required fewer anticonvulsants or smaller dosages after surgery. Therefore, 17 patients (49%) required less medication or no medication as a result of the surgical intervention. The number and quantity of anticonvulsants did not change significantly after surgery in 18 patients. Nine of 22 patients whose recent surgery was successful (grade 3 or 4) are still receiving anticonvulsants but are candidates for reduction or discontinuance of medications.

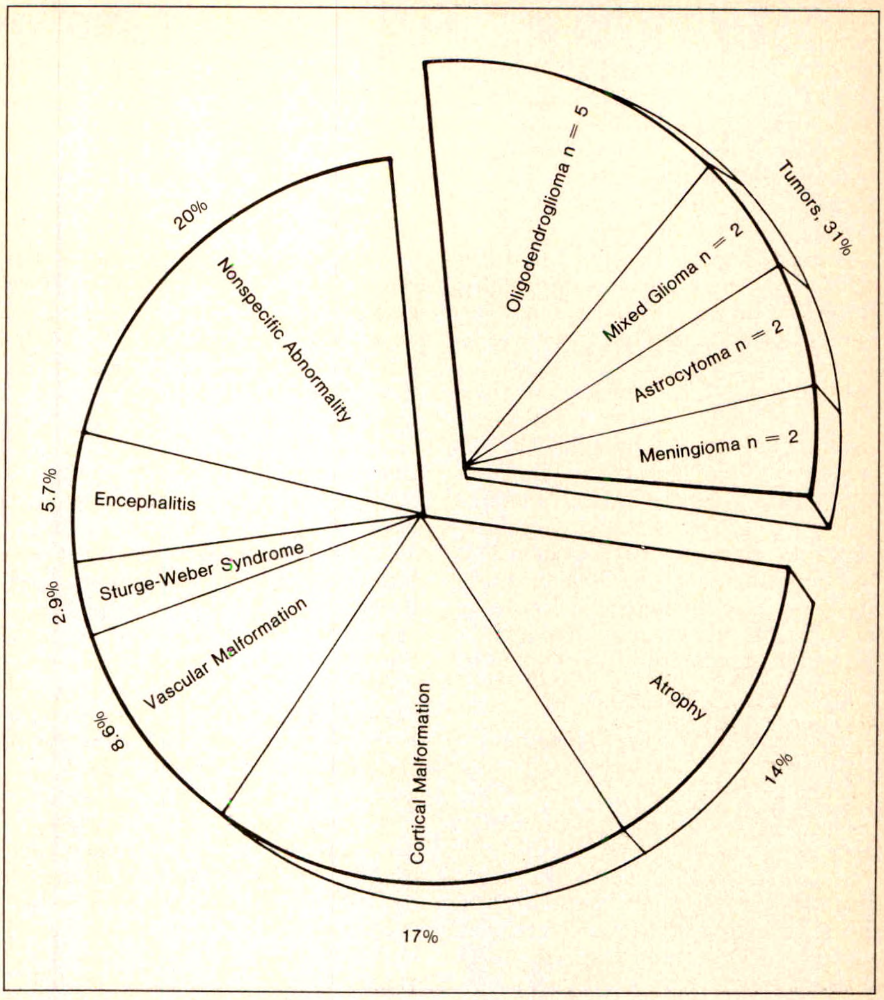
Other Operations

Four patients had two operations for epilepsy at The Children's Hospital during the time encompassed by this series, and for each patient the initial poor result was attributed to insufficient resection of epileptogenic cortex or tumor. The interval between operations ranged from 2 weeks to 5.8 years and averaged 1.8 years. The second operation yielded good results (seizure grade, 4) in two patients and minimal improvement in two others.

Two children in this series underwent brain biopsies prior to referral to The Children's Hospital. One, a child with a postherpetic cicatrix, had improved seizure control after cortical resection; the other had nonspecific pathologic changes and a poor surgical result. Another patient, who had chronic encephalitis, had a cortical resection at another institution 11 years after our initial operation; this second operation was without benefit.

Complications

Two patients were hemiparetic after surgery but improved sufficiently to be fully ambulatory. In both, the hemiparesis can be attributed to the extent of cortical resection required to remove a tumor. Visual field deficits following either temporal or occipital lobectomy were expected sequelae and were not considered to be complications. Hemianopia as a result of the removal of an occipital oligodendroglioma developed in one child; he became seizure free, but the visual field defect may have contributed to his being in a severe motor vehicle accident. No operative deaths occurred. Aseptic meningitis occurred in one patient. Complications not involving the nervous system included two patients with wound infections, two patients with postoperative hematomas, and one patient with thrombosis within the deep-venous system of one lower extremity.



Distribution of pathologic processes in 35 consecutive patients who underwent surgery for extratemporal epilepsy that began in childhood and who were selected for surgery by noninvasive criteria. The category of neoplasia is subdivided by specific tumor types.

Neuroradiology

Although many of these patients had no abnormality recognized on preoperative neurodiagnostic imaging, 27 (77%) of 35 had some identifiable abnormality on retrospective review. One or more neuroradiologic abnormality was present in each of 11 patients with neoplasia; five had a small localized mass affect, three had subtle mineralization, and five had an area of abnormal (low or high) density on CT. The neuroradiologic abnormalities in the brains of children with porencephaly were also diagnostic. Cerebral atrophy and cortical calcification were apparent on CT in the patient with Sturge-Weber syndrome.[25] Every patient with tuberous sclerosis had a radiographically apparent mass. The eight patients in this series without any (even very small) abnormality on retrospective review of neurodiagnostic imaging had the following pathologic diagnoses: nonspecific abnormality in four patients, cortical malformation (hamartoma) in two patients, and encephalitis in two others.

The postoperative mean seizure grade was 1.7 in patients without abnormality on neurodiagnostic imaging and 2.7 in those with abnormality.

COMMENT

Our observations indicate that among children with intractable seizures good results can follow corticectomy for extratemporal epileptic foci, using only noninvasive diagnostic methods for selection. Overall, 88.6% of our 35 patients experienced some improvement in the control of their epilepsy, and 62.9% had a good-to-excellent outcome (40% seizure free and 22.9% with only occasional seizures). If we consider only the later half of our study (those who underwent an operation after December 31, 1980), ie, the group operated on after CT and long-term monitoring with sphenoidal electrodes became available and hence the group most representative of our current selection of cases, 76.5% had a reduction in seizures of at least 75%. Benefit also came in terms of an improved ability to function in daily activities.

Most surgical series report good-to-excellent results in 70% to 90% of patients; however, such results are strongly biased by the very good outcome in patients undergoing temporal lobectomy.[11-14] The fact that extratemporal resections do not have nearly as good results[15-17] may explain why so little has been written about these patients. Compared with the information available on adults who underwent an operation for extratemporal partial epilepsy, our results, especially after 1980, are quite favorable.

Forty-three percent of our patients had an improved performance rating after surgery, in addition to improved control of seizures. Improvement in performance probably relates to patients having fewer seizures and/or their requiring less anticonvulsant medication (true for over 50% of our patients). Most who did not improve ("no change" category) were functioning well before surgery and, therefore, could not improve. Two patients had worse postoperative performance ratings; one had histologic evidence of encephalitis and the other had a frontal lesion contralateral to the site of the operation.

Noninvasive vs Invasive Preoperative Evaluation

Recently published studies of surgery for epilepsy have emphasized the value of invasive preoperative monitoring in the selection of patients.[13,26-32] Invasive testing with depth electrodes and/or surface recordings (subdural or epidural) requires additional surgical procedures, is expensive, and has associated risks of morbidity (eg, hemorrhage or infection).[33] Furthermore, many pediatric patients have a low tolerance for the usually long monitoring periods required.[13,29,30,32,34] We recognize the value of invasive preoperative monitoring in selected patients,[13,28-32] but it is important to identify the patients in whom these procedures can be avoided. Extracranial recordings made during multiple spontaneous seizures provided, in our patients, a reliable basis for localization of epileptic foci. The information that we obtained by careful analysis of ictal events recorded from the convexity and base of the skull via noninvasive techniques[35,36] and that obtained from intraoperative electrocorticography proved to be sufficient to guide surgical resection. Although the risk of erroneous localization or lateralization when relying heavily on extracranial electroencephalographic data is always present,[13] it is noteworthy that such events did not occur in our 35 consecutive patients who underwent surgery. Concordant structural anomalies on neuroimaging, which we did not require but frequently found, undoubtedly minimized this risk. Other criteria that influenced our selection of patients for surgery were constancy of an interictal EEG focus over several years[37] and clear compatibility of the neurologic and electrophysiologic findings with the functional profile obtained from neuropsychological assessment.[21-23] Consequently, without using invasive monitoring our results compare favorably with the published results from centers where recordings from depth or subdural electrodes weighed heavily in the selection of patients. Our experience is consistent with the view expressed by Ojemann and Engel,[38] Gloor,[39] and Olivier et al[30] that the risk-to-benefit ratio of investigation with depth electrodes should be carefully evaluated in each case and is rarely, if ever, required in patients who have both a structural abnormality on neurodiagnostic imaging and a corresponding epileptogenic focus in the EEG.

Our selection of cases improved over the time of accrual, as evidenced by the higher postoperative seizure scores in the latter half of the series (76.5% significantly improved). While some of this improvement may be attributed to learning from our own experience and the published experiences of others, we believe that most of the improvement is attributable to the introduction of long-term EEG monitoring and to advances in neurodiagnostic imaging.[40] These new technologies permitted better patient selection via more accurate localization of surgically accessible epileptogenic foci that, in turn, led to greater operative success. Future advances in neuroradiologic imaging, especially MRI[41-43] and positron emission tomography,[44-46] will probably enhance our ability to define anatomically epileptogenic foci and may restrict the need further for invasive electroencephalography.

Recording from depth and/or epidural electrodes can be helpful in discriminating an orbitofrontal focus from a focus in the mesial temporal lobe, however, during the span of this series we encountered this problem in only three patients. In two of these patients (operated on elsewhere and, therefore, not included in this study), recordings from epidural strip electrodes over the frontal and temporal convexity did not prevent false localization; a subsequent temporal lobectomy did not alter the frequency of seizures. However, in the third case, depth electrodes identified an orbitofrontal focus, and the patient did well after cortical resection. It is possible that some patients who would have benefited from surgery were not offered an operation because a focus that could have been identified by invasive recording was missed, ie, they were erroneously thought to have generalized epilepsy. While this possibility cannot be excluded, we believe that such cases were rare or nonexistent in our population of patients with seizures.

Most failures in surgery for epilepsy, whether dictated by pathology and anatomy, or secondary to an intentional conservative surgical approach, have been ascribed to insufficient localization and/or inadequate resection[47,48]; this is consistent with our experience. Therefore, we believe that the surgical failures encountered in this series after the introduction of long-term surface and basal EEG monitoring would probably not have been avoided by more invasive investigations. It is possible, however, that a few failures and the occasional need for a second operation could have been prevented by more extensive or better tailored resections guided by preoperative depth electrode encephalography, intraoperative stimulation of the cortex under local anesthesia, or preoperative mapping of the eloquent areas via implanted subdural grid electrodes.[13,30-32,38,41,49] When a discrepancy exists between EEG findings and neuroimaging or, in patients with negative neuroimaging, between neurological observations and the EEG findings, then invasive monitoring seems mandatory. Also, the existence of multilobar lesions in patients not qualifying for hemispheral surgery is another clear indication.

It is widely believed, contrary to our observations, that neuroradiographic abnormalities in patients with intractable epilepsy are rare unless there is a mass.[13,50] However, subtle but definite enhancement can often be recognized on CT in patients with nonneoplastic epileptogenic foci in frontal lobes, when no abnormality is apparent on the noncontrasted images.[42] In Goldring's[51] series, seizure foci were localized with radiographic studies in five of 10 patients, and, in other cases, "partial localization" was achieved. These observations would seem to indicate that neurodiagnostic imaging can have an extremely important role in the preoperative evaluation of patients with partial epilepsy.[40] Retrospective review of preoperative neuroimaging revealed that over 75% of our patients had focal, usually nondiagnostic, radiographic abnormalities that correlated with the EEG localization. Such a large percentage is probably a reflection of the pathologic findings (eg, tumors, malformations, and atrophic lesions) that were common in our population and, perhaps more frequently, the cause of chronic intractable epilepsy in children. In the absence of focal lesions, a lateralizing radiographic abnormality (eg, atrophy) was common and often provided reassuring corroboration of EEG localization.

Frontal Lobe Epilepsy

Most series of surgically treated epilepsy, especially that beginning in childhood, report small numbers of frontal lobe operations[7,52,53]; only 10% of operations for seizures at the Montreal (Quebec) Neurological Institute involved the frontal lobe.[54] Forty percent of our 35 consecutive patients with extratemporal epilepsy who underwent an operation had epileptogenic foci involving frontal lobe.

The surgical treatment of frontal lobe epilepsy in our experience and in prior reports[16,17,28,55] is less successful than the treatment of either temporal lobe epilepsy or widespread epileptogenic foci requiring hemispherectomy or hemicorticectomy. Nevertheless, 64% of our patients with frontal lobe seizures were significantly improved by surgery. In particular, surgery was successful when radiologic abnormalities corresponded to the seizure focus.

Extensive Hemispheric Abnormality

These cases had the lowest percentage of significantly improved individuals among the anatomically defined categories. Only 46% (6/13) of patients with multilobar resections experienced significant improvement in the control of their seizures. In contrast, our experience with hemicorticectomy (not included in this report) has been much more gratifying. Although some clinical and pathologic differences exist between those who underwent multilobar resection and those who had undergone a hemispheral cortical resection, this observation suggests that the outcome is improved when an extensive surrounding area of cortex can be removed along with the identified epileptogenic tissue. This notion concerning the extent of resection in patients with large hemispheral lesions is consistent with Rasmussen's observation[16] and analogous to the impressions of Van Buren et al[50] on temporal lobe surgery, ie, that limited resection results in less satisfactory control of seizures.

Pathology

Differences in the distribution of pathologic findings between our group of patients and other series of patients with surgically treated epilepsy are not easily explained; however, it is clear that they represent quite dissimilar populations. Bias, whether introduced by patients (families), referring physicians, neurologists, or neurosurgeons, affects the selection of patients for surgery and hence the types of pathologic findings represented. As an alternative, it is interesting to speculate that the underlying processes causing chronic partial epilepsy may have changed over time.

The high proportion of our patients with tumors (34% of the total) is noteworthy and surprising. Our patients with tumor had chronic epilepsy for as long as 25 years (mean, 7.7 years) and, as in other series of surgically treated epilepsy,[16,56,57] the convulsive disorder, not progressive neurologic deficit or intracranial hypertension, was the primary operative indication. While the Montreal, Quebec, Oxford, England, and other groups reported tumors in close to 20% of their patients with intractable seizures,[16,27,54,57] the incidence of neoplasia was much lower in earlier pediatric series.[11,52] Nevertheless, more recent series of operatively treated epilepsy have included a somewhat larger proportion of neoplasms.[58,59] Goldring et al[60] observed that low-grade gliomas detected by CT are a frequent cause of chronic seizure disorders. Although Rasmussen[4,61] reported a high likelihood of tumor in children who came to surgery with intractable epilepsy, the opposite is reported in other pediatric series.[62,63] It is possible that slowly growing and otherwise asymptomatic brain tumors may be a more frequent cause of protracted seizure disorders in children than in adults.

Our patients with nonneoplastic pathologic findings were also significantly different from those described in other articles. Although reports on the incidence of cicatrix as a cause of intractable seizures have ranged from 4% to 20%,[16,29,52] we found only one among 35 consecutive patients who underwent surgery.

Our limited experience with chronic encephalitis (two patients) was disheartening; surgery brought no benefit. The outcome was also poor in two other patients with epilepsia partialis continua who may have had encephalitis but whose histologic features warranted only a "nonspecific" classification. Although others have published similar results in encephalitis,[64] more encouraging surgical outcomes have been reported also.[49,50,63] Of such cases, 15% to 30% may be cured,[51,52,65] especially if the surgical resection is extensive (eg, hemispherectomy) and done after progression of the encephalitic process has ceased, which was not true in our cases.[56,66]

Timing of Surgery

There would seem to be considerable advantage, in terms of limiting human suffering, by controlling seizures as early in life as possible. No inherent reason exists to delay surgery for seizures in patients who meet reasonable criteria. A long latency between the onset of epilepsy and surgery may predispose to poorer postoperative seizure control, particularly when the underlying pathologic process is neoplasia. The observations, albeit on few patients, that those with greater preoperative duration of seizures tended to have poorer results suggest that the duration of extratemporal partial seizures may influence the outcome from surgery; consequently, an earlier operation may lead to better results. This interpretation is consistent with the concept of kindling and secondary epileptogenesis.[67,68] A series that is very much larger would be necessary to definitively answer this question. The high incidence of unsuspected tumors in refractory partial epilepsy of childhood is another reason to favor early surgery; results should be more favorable in patients with neoplasia if the operation is performed at a time when the neoplasm is smaller or, perhaps, less anaplastic. However, when the underlying pathologic process is a smoldering inflamation, early surgical intervention is likely to be unsuccessful[56,66]; outcome is also unfavorable in patients with nonspecific pathologic processes, probably because the abnormality extends beyond the limits of the resection.

In retrospect, we believe that relatively few of our cases were operated on at the optimal age; surgery was delayed in most patients much longer than necessary. The fact that results were usually satisfactory in our patients who underwent surgery beyond adolescence means that there were probably years of needless suffering from epilepsy and the effects of antiepileptic medications. Paradoxically, patients with anatomically well-defined and nonprogressive lesions (eg, vascular malformations) often had the longest delay between onset of seizures and surgery. It seems reasonable to believe that these patients, usually free of seizures after surgery and free of neurologic deficits before and after surgery, would have benefited greatly from earlier intervention.

P300 Brain Activity in Seizure Patients Preceding Temporal Lobectomy

Charles A. Nelson, PhD; Paul F. Collins; Fernando Torres, MD

• Event-related potentials were recorded over occipital and parietal scalp from 20 patients suffering from intractable partial complex seizures prior to undergoing a temporal lobectomy. Subjects were presented with language and nonlanguage visual stimuli using a divided-field, "oddball" paradigm. Although behavioral performance (button-press accuracy, reaction time, and running counts) was comparable across all groups (although accuracy was worse for those in the left temporal group), patients showed tremendous variability in both the amplitude and latency of the P300 response. Particularly notable was the observation that more slow wave activity was present among the patients than among the control subjects, and those scheduled for a left temporal resection evinced more amplitude reduction than those scheduled for a right temporal resection. In addition, a number of patients appeared not to show a P300 response at all. These results are discussed in the context of the utility of using noninvasive event-related potential measures to examine both memory impairment and the integrity of the neural structures that mediate memory functioning in certain patient populations.

(*Arch Neurol.* 1991;48:141-147)

The recording of endogenous brain activity as reflected by event-related potentials (ERPs) has provided a useful metric for assessing a variety of cognitive abilities in the human adult.[1] Of the many components that have been studied, the P300 response has received the most attention.[2,3] The P300 is a positive-going wave of the ERP with a latency greater than 250 milliseconds (although it generally occurs between 300 and 600 milliseconds after stimulus onset), is most pronounced at parietal scalp, and is not specific to any one sense modality.[4] Although unanimity on the meaning of the P300 wave is absent, a large body of research suggests that the response indexes some form of explicit or declarative memory, such as a subject's overt attempt to update working memory.[5-6]

Considerable attention has been directed toward the study of the neural structures responsible for generating the P300 response. For example, using noninvasive measures of magnetic activity (superconducting quantum interference device [ie, SQUID]) in neurologically normal individuals, Kaufman and colleagues[7] have reported neuromagnetic correlates of the P300 wave generated in the hippocampus. Similarly, Halgren,[8,9] McCarthy and Wood,[10] McCarthy and colleagues,[11] Stapelton and Halgren,[12] and Wood et al,[13] using indwelling electrodes in epileptic populations, have also reported P300 correlates generated in medial temporal lobe (MTL) structures (the hippocampus in particular), although there is some disagreement as to exactly where in the hippocampus this response originates,[8-13] and whether the hippocampus is the only source of scalp-recorded P300 activity.

If the proposal is correct that the P300 wave reflects a form of explicit or declarative memory that is mediated by MTL structures, this late ERP component should, in principle, have tremendous clinical utility in assessing certain forms of memory impairment, as well as the integrity of the MTL structures that support explicit memory. An example of a population that might profit from such an examination is patients suffering from intractable partial complex seizures. For example, Puce et al[14] reported that 81% of individuals with unilateral temporal lobe epilepsy manifested little, if any, P300 activity ipsilateral to the seizure focus, although prominent P300 activity was evident in most of these same individuals from the nonepileptogenic lobe. These findings were obtained from depth electrodes implanted in the hippocampi and are in agreement with other reports using comparably invasive measures.[9] To date, however, there are no extant studies in which this issue has been examined noninvasively before surgery. In this article, we discuss the findings from a comparable group of patients observed using surface-recorded ERPs before undergoing a temporal lobe resection.

PATIENTS AND METHODS

Twenty patients scheduled for either a left temporal lobectomy (LTL) (n = 10) or a right temporal lobectomy (RTL) (n = 10) served as subjects. Five strongly right-handed normal volunteers served as controls. Informed consent was obtained from

all subjects after the experimental procedures had been explained. The neuropsychological and medical profiles of the patients are illustrated in Tables 1 and 2. As is seen in Table 1, the amobarbital sodium procedure indicated left hemisphere dominance for language in 19 patients (although three of these had had some right hemisphere language function) and right-hemisphere dominance in one patient (patient 10). All patients underwent surgery after being tested.

Silver chloride electrodes were attached to the scalp with collodion at O_1, O_z, O_2, P_3, P_z, and P_4 according to the International 10/20 System and referenced to linked earlobe electrodes. A ground silver chloride electrode was placed on the forehead. All impedances were less than 5 kΩ. A bipolar electro-oculogram (EOG) was recorded using miniature electrodes placed on the supraorbital ridge and the outer canthus of the right eye. Impedances for the eye electrodes were generally below 5 kΩ.

Both electroencephalographic (EEG) and EOG signals were amplified and filtered (model 125A5, Grass Instruments, Quincy, Mass). For the EEG, gain was set to 100 000, while for the EOG gain was set to 5000. For both EEG and EOG, the band-pass filter was set at 0.1 to 30 Hz, with a 60-Hz notch filter in place. All signals were monitored on-line by a signal averager (Tracor Northern Signal Averager, Northern Scientific Inc, Madison, Wis) configured as a scope, and were digitized on-line every 5 milliseconds (200 Hz) for 1100 milliseconds, beginning 100 milliseconds before the presentation of the stimulus (pre-event baseline).

Subjects were seated in a chair in front of a rear-projection screen. Side panels occluded the subject's peripheral vision, and all testing took place in the dark. Stimuli (see below) were rear projected onto the half-field screen for 100 milliseconds. The interval between trials varied randomly between 500 and 1000 milliseconds.

The stimuli consisted of black-and-white slides of the word *bat* presented in uppercase letters and a set of *Chinese characters*. (The stimuli and experimental design were selected as part of a series of studies attempting to assess the lateralization of language function, an objective that is not central to the data discussed herein. See reference 15.) Each of these stimuli was embedded in a checkerboard matrix containing twenty-two 1-cm checks along the vertical axis and twenty-eight 1-cm checks along the horizontal axis (ie, a 22 × 28-cm array of checks). The density of the two stimuli (in terms of factors such as character width and lines per millimeter) was comparable, and the stimuli were matched for luminance. The word bat and the Chinese characters each subtended approximately 5 degrees 5 minutes when viewed from a distance of 90 cm; the entire slide (ie, including the checkerboard field) subtended 18 degrees 4 minutes horizontally and 13 degrees 30 minutes vertically when viewed from this same distance. The stimuli were presented on a half-field screen with each stimulus aligned with the center fixation point and moving outward left or right.

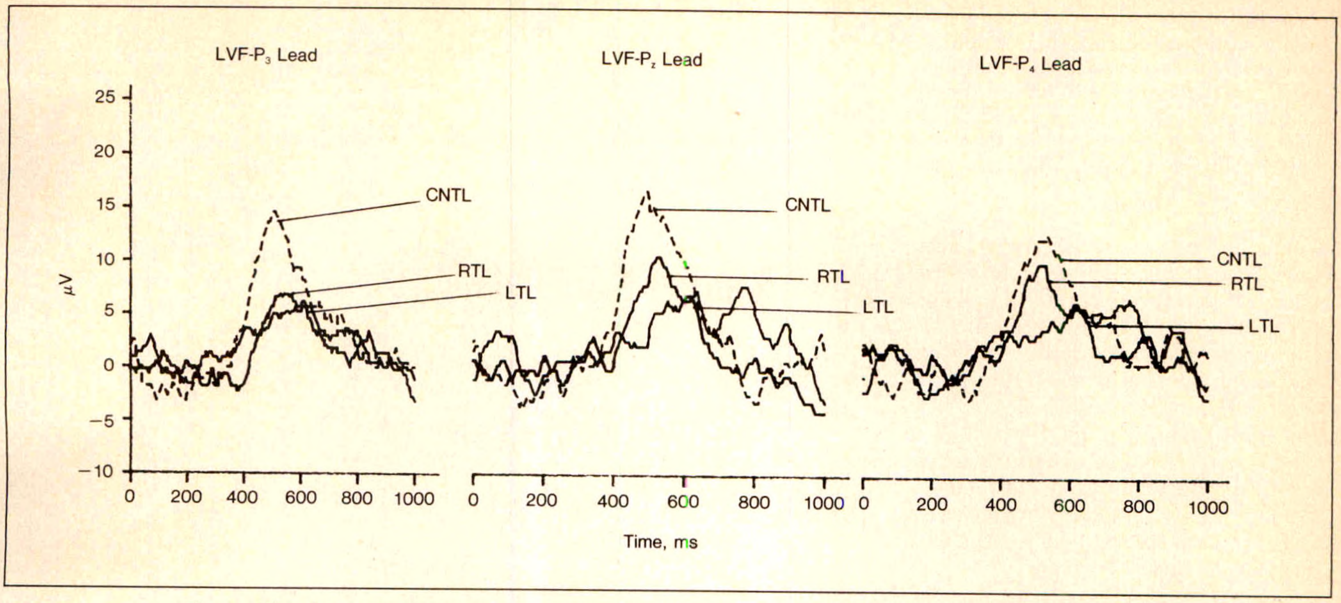

Fig 1.—Grand-average difference waveforms (80% nontarget subtracted from 20% target) for control subjects (CNTL) (dashed line), those who underwent a left temporal lobectomy (LTL) (light solid line), and those who underwent a right temporal lobectomy (RTL) (dark solid line) to left visual field (LVF) presentations of the word *bat* for left parietal (P$_3$), midline (P$_z$), and right parietal (P$_4$) leads. The grand average was computed by averaging each subject's average response (n = 5 for control subjects and n = 10 for each of the two patient groups). Note ordering of P300 amplitude, with control subjects showing most amplitude followed by those who underwent an RTL and then those who underwent an LTL. Positive is up.

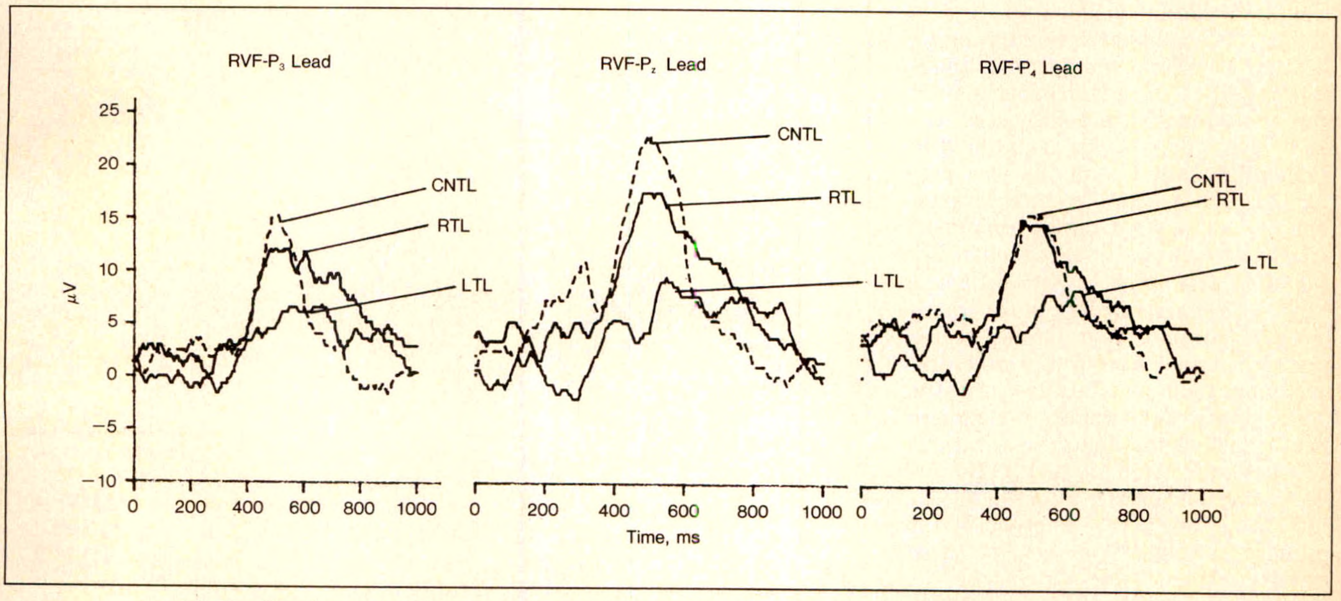

Fig 2.—Grand-average difference waveforms (80% nontarget subtracted from 20% target) for control subjects (CNTL) (dashed line), those who underwent a left temporal lobectomy (LTL) (light solid line), and those who underwent a right temporal lobectomy (RTL) (dark solid line) to right visual field (RVF) presentations of the word *bat* for left parietal (P$_3$), midline (P$_z$), and right parietal (P$_4$) leads. The grand average was computed by averaging each subject's average response (n = 5 for control subjects and n = 10 for each of the two patient groups). Note ordering of P300 amplitude, with control subjects showing most amplitude followed by those who underwent an RTL and then those who underwent an LTL. Positive is up.

Subjects were tested with the two stimuli paired in a simple 20%-80% "oddball" task. Each stimulus served as a target (random 20% occurrence) and as a nontarget (80% occurrence) event separately within two trial blocks of 200 trials each. Subjects received four such trial blocks, two of which involved stimulating the right visual field and two of which involved stimulating the left visual field, producing a total of 800 trials presented to each subject. The order of presentation was counterbalanced across subjects. Subjects were asked to push a button, using their preferred hand, whenever a target appeared; they were also asked to keep a running count of the targets. At the end of each condition, the patient reported this count to the experimenter.

Artifact Rejection

Any trial that contained an EOG signal that exceeded 25 µV resulted in rejecting the entire trial from subsequent analysis.

Any EEG signal that exceeded analog-to-digital values for more than 50 milliseconds at a given lead resulted in rejecting the data from that lead; if artifacts occurred at more than two leads, the entire trial was rejected. In this manner, only artifact-free data were used in the final data analysis.

RESULTS

The findings of the control subjects have been reported in detail elsewhere[15]; therefore, these data will only be abstracted here. In addition, although a stimulus factor (ie, the word bat vs the Chinese characters) was entered into most statistical analyses, the discussion will be restricted to when the word bat served as the target event, as discrimination between patient groups was always stronger for this stimulus than it was for the Chinese characters.

Summary of Control Subjects' Performance

In brief, the analysis of the control subjects' behavioral data revealed that running counts of target presentations (n = 40 in each condition) were nearly perfect, as was button-press accuracy ($M = 39.8$ and 39.4 for the right visual field and the left visual field, respectively). As would be expected, running counts, accuracy, and reaction times did not differ across the experimental manipulation (eg, accuracy was the same regardless of the visual field to which the target stimulus was presented). With regard to the ERP data, control subjects evinced prominent P300 activity to all target events. Restricting discussion to parietal leads, where P300 activity was most prominent, the amplitude difference scores for right-handed subjects were larger and more strongly lateralized over the left, language-dominant hemisphere for right visual field presentations (10.8 μV at P_3 vs 8.0 μV at P_4) than for left visual field presentations (8.6 μV at P_3 vs 7.4 μV at P_4). (See reference 15 for a more complete discussion of these results.)

Patient-Subjects' Performance

Behavioral Performance.—Patients' running counts were generally accurate across all conditions. Data analysis was, therefore, restricted to button-press accuracy and the resulting reaction times.

Button Press Accuracy.—A Group (LTL or RTL) × Visual Field (left or right) × Stimulus (the word bat or the Chinese characters) repeated-measures analysis of variance (ANOVA) was computed on button-press accuracy. This analysis revealed a significant interaction between group, visual field, and stimulus ($F = 7.14$ [1,18], $P < .02$). Specific follow-up tests (the Newman-Keuls procedure for Student's t test) revealed that the two patient groups did not differ from one another in their responses to the word bat presented in the right visual field ($M = 37.4$ and 37.3 for right and left temporal lobe groups, respectively). However, those in the left temporal lobe group performed significantly worse than did those in the right temporal lobe group in their responses to the word bat presented in the left visual field ($M = 40.0$ and 35.1 for right and left temporal lobe groups, respectively).

Reaction Time.—Mean reaction

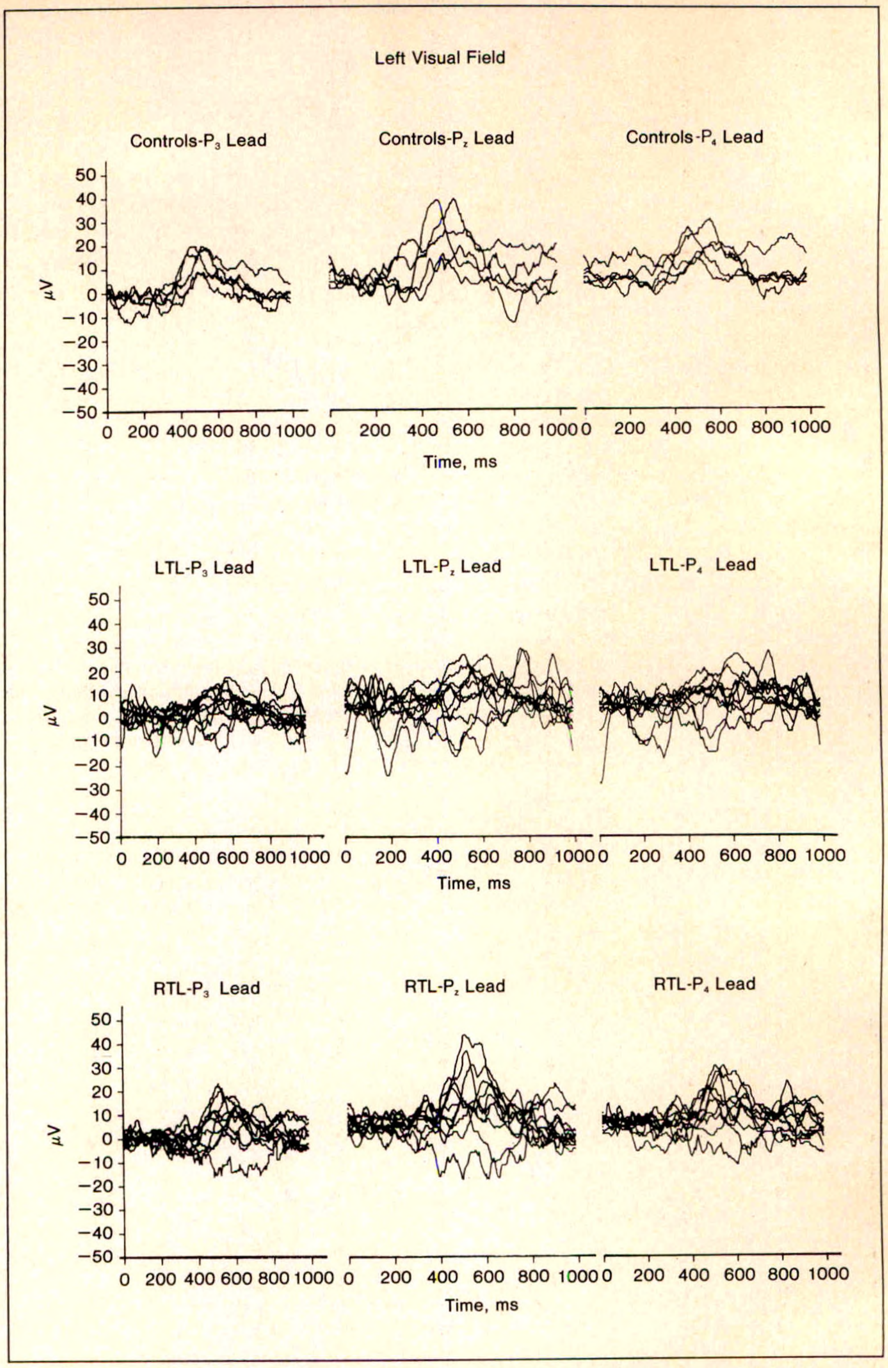

Fig 3.—Superimposition of each subject's average against all other subjects' averages for control subjects (top panel), those who underwent a left temporal lobectomy (LTL) (middle panel), and those who underwent a right temporal lobectomy (RTL) (bottom panel) to left visual field presentations of the word *bat* for left parietal (P_3), midline (P_z), and right parietal (P_4) leads. Each average was computed by averaging all artifact-free trials. The data displayed are for the five control subjects and for the 10 LTL and 10 RTL patients. Positive is up.

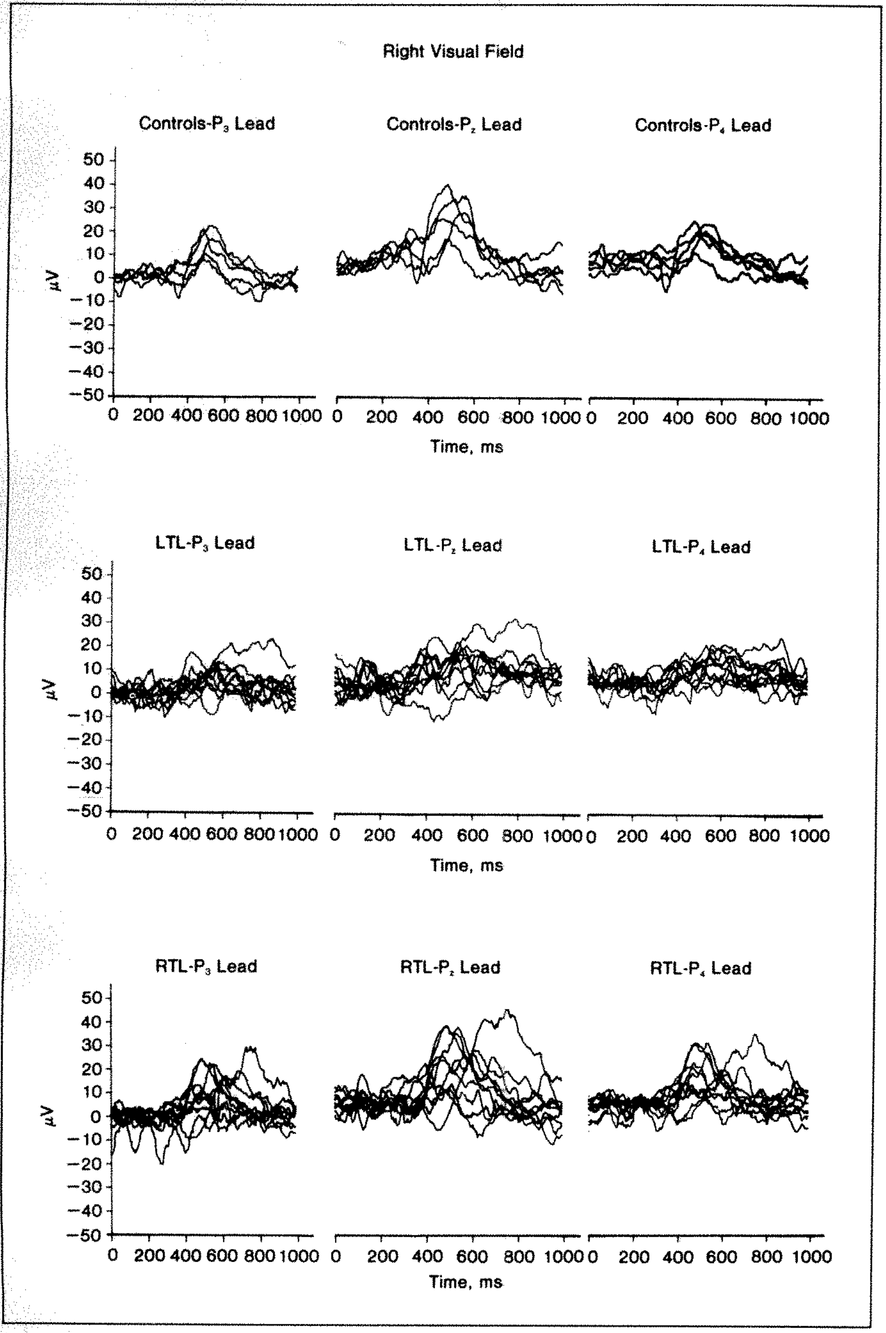

Fig 4.—Superimposition of each subject's average against all other subjects' averages for control subjects (top), those who underwent a left temporal lobectomy (LTL) (middle), and those who underwent a right temporal lobectomy (RTL) (bottom) to right visual field presentations of the word *bat* for left parietal (P_3), midline (P_z), and right parietal (P_4) leads. Each average was computed by averaging all artifact-free trials. The data displayed are for the five control subjects and for the 10 LTL and 10 RTL patients. Positive is up.

times for the word bat to both visual fields for the two patient groups and the control group ranged from 588 to 601 milliseconds; a repeated-measures ANOVA computed on reaction times identical to those computed on button-press accuracy revealed no significant differences between the two patient groups.

ERP Analyses.—Difference waveforms were computed via point-by-point subtraction of average nontarget from average target waveforms in each condition (Figs 1 through 4). The grand-average difference waveforms at parietal leads for patient and control subjects can be seen in Figs 1 and 2; Figs 3 and 4 present each subject's average waveform superimposed on the average waveforms of all other subjects in the group.

Inspection of Figs 1 and 2 reveals that the patients' grand-average difference waveforms are more irregular and less sharply peaked than are those of the control subjects. Reduced amplitude in the P300 latency range is also evident, particularly for the LTL patients. However, the most notable differences between the patient and control groups can be seen in Figs 3 and 4. Here, it is evident that the difference waveforms are considerably more variable among the patients than they are among the control subjects in terms of both the clarity and the latency of P300 peak amplitudes; overall, LTL waveforms appear to be more clearly deviant from control waveforms, especially with right visual field presentations (Fig 4).

Because many patients' ERPs contained slow-wave activity rather than peaked components, areas were integrated relative to the prestimulus baseline for amplitude deflections in the interval between 300 and 1000 milliseconds. These areas were calculated separately on target and nontarget ERPs within each experimental condition, and statistical analyses were performed on difference scores computed by subtraction of nontarget areas from target areas. A Group (LTL or RTL) × Visual Field (left or right) × Stimulus (the word bat or the Chinese characters) × Lead (O_z and P_z) repeated-measures ANOVA of these area difference scores revealed a significant interaction between visual field and group for the midline leads (F = 5.61 [1,18], $P < .05$). An identical ANOVA for the lateral leads (O_1, O_2, P_3, and P_4) revealed a somewhat smaller effect for the same interaction (F = 3.70 [1,18], $P < .07$). Specific follow-up tests (the Newman-Keuls procedure for Student's *t* test) revealed that right visual field presentations of the word bat invoked much larger P300 area-difference scores at parietal leads for the RTL group than for the LTL group; in contrast, RTL responses decreased during left visual field presentations of the word bat while LTL responses increased slightly. These findings are illustrated in Table 3 and in Fig 5.

Statistical analysis of both patient and control ERPs was not conducted, because ANOVAs have little power to detect differences when groups are relatively small and unequal in size, as in this study. However, when patients' area-difference scores were inspected relative to those of the control subjects, the trend across lateral parietal leads was for right visual field presen-

Table 3.—Mean ERP Area Difference Scores*

	Left Visual Field		Right Visual Field	
Lead	LTL	RTL	LTL	RTL
O_1	86 (1182)	500 (1546)	1083 (2167)	2315 (3176)

P_4	1241 (2136)	1411 (3254)	1422 (850)	3010 (3674)

*Event-related potentials (ERP) areas were integrated relative to prestimulus baseline for sustained amplitude deflections in the interval from 300 to 1000 milliseconds. See text for computation of difference scores. Means are displayed only for blocks of trials in which the word *bat* was the target stimulus. Standard deviations are in parentheses. LTL indicates left temporal lobectomy; RTL, right temporal lobectomy.

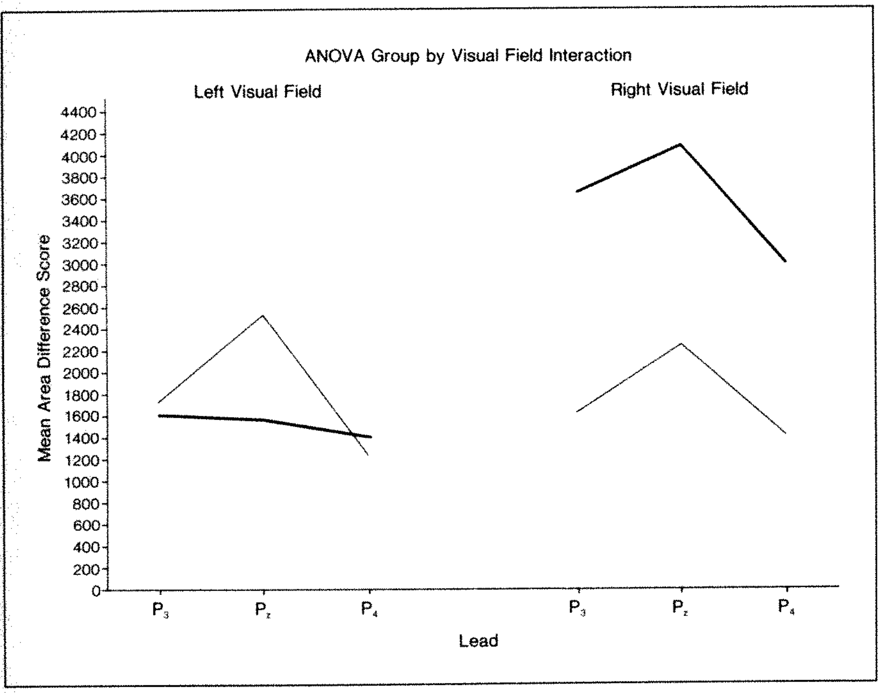

Fig 5.—Illustration of mean area difference scores for Group (right temporal lobectomy [RTL] or left temporal lobectomy [LTL]) × Visual Field (right or left) interaction reported in text. The thick line represents the responses of patients scheduled for an RTL, while the thin line represents the responses of patients scheduled for an LTL. ANOVA indicates analysis of variance.

tations of the word bat to invoke the greatest area-difference score for the RTL group, followed by the control subjects (46% smaller than RTL group) and then the LTL group (67% smaller than RTL group). With left visual field presentations of the word bat, area-difference scores for the RTL and control groups were both reduced relative to right visual field presentations of the word (44% and 4% smaller, respectively); however, the LTL group scores increased (30% larger).

Relation Between Patients' ERPs and Verbal Memory Neuropsychological Profile.—An examination of patients' Wechsler Memory Scale scores suggested that memory impairment was reflected by two different ERP manifestations, and that these occurred primarily when stimuli were delivered to the affected hemisphere of each patient. Specifically, verbal memory impairment in the LTL group was related to decreased P300 area, as indicated by moderate positive correlations of activity at the left parietal lead during right visual field presentations with immediate and delayed Logical Memory scores (.41 and .35 for immediate vs delayed recall, respectively). In contrast, verbal memory impairment in the RTL group was related to increased P300 area, primarily in the form of diffuse slow-wave activity in target waveforms, as indicated by negative correlations of parietal activity during left visual field presentations with the same Logical Memory recall scores (−.52 and −.63 for immediate and delayed recall, respectively). In this context, one RTL case can be seen in Fig 3 as an outlier with markedly delayed, predominantly slow-wave activity only when the word bat was presented in the right visual field. This RTL patient (excluded from the correlations above) demonstrated significant verbal memory impairment on the Wechsler Memory Scale as well as partial right hemisphere language representation on the amobarbital sodium procedure.

COMMENT

Unlike the control subjects, patients did not display significant patterns of lateralized scalp P300 activity in response to the right vs left visual field presentations of a verbal stimulus, despite the fact that 19 of 20 patients were left hemisphere dominant for language (as, presumably, were the right-handed control subjects). Instead, a less precise effect of visual field alone was observed in that RTL patients displayed greater P300 activity across all parietal leads in response to right visual field stimulus presentations. Such findings are not surprising, considering the morphological differences in the P300 activity recorded in the patients relative to the control subjects. Although most RTL patients displayed a "control-like" P300 peak in response to half-field presentations of a verbal stimulus, this deflection contained considerable overlapping slow-wave activity as well. Moreover, LTL patients displayed an irregular waveshape and a general reduction in P300 area that was most noticeable when the word bat was presented to the left (dominant) hemisphere. The relatively slower and more irregular ERP activity of the patients apparently impeded localization of verbal memory effects in terms of scalp topography, since such localization was achieved using the clearly defined P300 peaks of control subjects.[15]

Aberrant P300 activity among our LTL patients is consistent with reports of P300 reduction, measured intracranially, ipsilateral to seizure focus,[11,14,16] although the current scalp-recorded effects depended on half-field stimulus presentations rather than electrode recording sites. The restriction of P300 amplitude reduction to LTL patients only is also consistent with their relatively greater neuropsychological impairment (Table 1) and the verbal content of the oddball task. Presumably, RTL patients would have demonstrated reduction in P300 amplitude if a purely abstract (unnameable) spatial stimulus had been employed, as compared with the Chinese characters serving as a linguistic control stimulus in the current study.

The scalp-recorded effects for the LTL group are quite comparable with those noted by Puce et al,[14] who recorded P300 activity in patients using indwelling electrodes. In this context, our findings are encouraging in two respects. First, additional support is now provided for the proposition that measurement of P300 activity can be used to assess the integrity of the neural structures that underlie explicit memory. Second, it appears that this assessment can be accomplished noninvasively, provided that appropriate experimental manipulations are employed, such as half-field presentation of verbal and nonverbal material. A more clinically relevant extension of the methodology in this study would be to employ a more complex task using verbal and nonverbal stimuli from neuropsychological tests with demonstrated sensitivity to lateralized or "material-specific" memory processes. For example, one could pretest patients with lists of words and unnameable shapes from short-term memory tasks (eg, the Logical Memory and Visual Reproduction subtests of the Wechsler Memory Scale) and then conduct ERP testing in which patients are required to discriminate half-field presentations of previously unencountered words and shapes from those encoded during pretesting.

Although this report is, to the best of our knowledge, the first to describe P300 activity recorded noninvasively in patients with temporal lobe partial seizures prior to surgery, note that similar work has been done with patients many years after they underwent a temporal lobectomy. In this line of investigation, Johnson[17-19] has reported that P300 amplitude and latency in individuals who had undergone unilateral resection of the temporal lobe (including the pes, uncus, amygdala, and the anterior portion of the hippocampal complex) were similar to those of normal control subjects. The current results suggest that P300 morphologic activity is considerably more irregular and variable in patients prior to undergoing a temporal lobectomy than it is in neurologically intact individuals. Furthermore, our results suggest that memory impairment may be manifested in various alterations of ERP morphology, which are generated by the interaction of a patient's specific underlying neural dysfunction with the specific nature of the memory task imposed. Both preoperative and postoperative testing, therefore, appears to be necessary before inferences can be drawn regarding memory functions and generators of scalp-recorded ERP components in epileptic populations.

Research and manuscript preparation were supported by grants to Dr Nelson from the following: the National Institutes of Health (NIH), Bethesda, Md (HD23389); the McKnight-Land Grant Endowment of the University of Minnesota, Minneapolis; a training grant from the NIH (HD07151) to the Center for Research in Learning, Perception, and Cognition, University of Minnesota; an award from the Joseph P. Kennedy Foundation, Washington, DC; and the Minnesota Comprehensive Epilepsy Program, Minneapolis.

Cognition-Independent Neurologic Symptoms in Normal Aging and Probable Alzheimer's Disease

Emile H. Franssen, MD; Barry Reisberg, MD; Alan Kluger, PhD; Elia Sinaiko, PhD; Conrado Boja, MD

• Deep tendon reflexes, plantar responses, muscle tone, and release signs were studied as 14 individual clinical variables and as five summary variables in 135 aged subjects, including 27 control subjects, 20 subjects with mild cognitive impairment, and 88 subjects with successive stages of probable Alzheimer's disease. Changes in activity of elicited responses were rated on a seven-point scale. Results were analyzed both as prevalence and mean degree of change in activity. Rating on a variable combining all 14 individual variables was significantly higher in a group with mild cognitive impairment than in a control group. Subjects with an early stage of Alzheimer's disease had both higher prevalence of increased activity and increased mean scores of deep tendon reflexes and muscle tone. They had a higher prevalence of increased activity on a variable combining three release signs. Patients with a late stage of Alzheimer's disease had significantly increased prevalence and mean scores of muscle tone and grasping and sucking reflexes compared with control subjects and patients with the early stage of Alzheimer's disease.

(*Arch Neurol.* 1991;48:148-154)

Alzheimer's disease (AD) is an insidious and slowly progressive form of dementia with widespread and characteristic neuropathologic changes.[1-3] In a majority of cases, gross impairment of motor function is not obvious in the early stages of the illness. Ambulation is not seriously impaired until language and other cognitive processes have been severely compromised,[4-6] but in the late stage of the illness it declines rapidly.[5,6]

Changes in deep tendon reflexes, plantar responses, and muscle tone may be early signs of disturbed motor function, but they can also accompany normal aging.[7] Increased muscle tone has been reported as the most common motor abnormality related to increasing severity of dementia in patients with probable AD.[8] Release signs (also referred to as primitive, developmental, or neonatal reflexes, or, alternatively termed, cortical or frontal disinhibition signs) are commonly associated with dementia, but may also occur in healthy elderly individuals.[9-16] They are strongly associated with the severity of dementia.[17]

Reflex testing ranks as the premier objective measure of nervous system integrity.[7] Reflexes can be evaluated throughout the entire course of dementia, including the end stage when cognitive testing results in uniform bottom scores.[18-20] As such, they may be useful as independent markers of disease progression and as indicators of potential therapy.[21]

The existing literature shows considerable variability in reported incidence and significance of specific release signs in dementia. Possible explanations are differences in the stage of dementia during which these signs are elicited, differences in methods or scoring, and inclusion of dementia of various causes.

We report the results of a cross-sectional investigation of deep tendon reflexes, plantar responses, muscle tone, and release signs rated on a seven-point activity scale in a group of 135 elderly subjects. Because it is important to eliminate changes associated with normal aging, we have included a control group of healthy community-residing and well-functioning aged subjects. The study group encompasses the entire range of subjects from healthy normal elderly and mildly cognitively impaired subjects to patients with end-stage AD.

SUBJECTS AND METHODS

Subjects

We studied 135 consecutive community-residing and nursing home-residing elderly persons, including normal elderly control subjects with and without subjective memory impairment ($n = 27$), patients with mild objective cognitive impairment ($n = 20$), and patients with AD in all stages of severity ($n = 88$). All cognitively impaired patients had been living normal lives before the onset of their illness. Their mean educational level was 13.1 years. Informed consent was obtained after the nature of the procedure had been fully explained. All patients with the diagnosis of AD fulfilled the National Institute of Neurological and Communicative Disorders and Stroke–Alzheimer's Disease and Related Disorders Association criteria for a clinical diagnosis of probable Alzheimer's disease.[22] All subjects underwent neurologic, psychiatric, and physical examinations, as well as a comprehensive neuropsychological test battery, selected for its sensitivity to cognitive deficit in aging and dementia, including tests for evaluation of recent memory, attention, psychomotor speed, language, visuospatial function, and praxis. Also for all subjects, electrocardiograms; routine laboratory tests including thyroid function, serum B_{12} and folate levels; and either computed tomographic or magnetic resonance imaging scans of the brain were performed. Excluded from the study were all individuals with conditions known to adversely affect cognition or functioning, ie, patients with a history of head trauma with resulting neurologic sequelae, history of seizures prior to the onset of AD, Parkinson's disease with its onset prior to the onset of AD, mental retardation, psychosis, or depression, as well as patients with vascular dementia whose Modified Ischemia Scale score was 4 or greater,[23] patients with evidence of Binswanger's disease, and patients

with peripheral neuropathy or with significant arthropathy. Table 1 shows the demographic characteristics of subjects at the time of their examination. There were no differences in racial or ethnic makeup in any clinical severity group.

Measures

The severity of cognitive and functional impairment was assessed using the Global Deterioration Scale (GDS)[24] and the Mini-Mental State Examination (MMSE).[25] Table 1 shows the GDS scores with corresponding mean MMSE scores of the study subjects. The GDS stages can be summarized as follows: GDS 1, no subjective complaints of memory deficit and no memory deficit on clinical interview; GDS 2, subjective complaints of memory deficits with no objective deficits in employment or social situations; GDS 3, earliest clear-cut deficit with objective evidence of deficit on detailed interview and decreased performance in demanding employment and social settings; GDS 4, clear-cut deficit on careful clinical interview manifest in such areas as decreased knowledge of current and recent events and concentration deficits on serial subtractions, with decreased ability in performance of complex tasks such as managing finances or preparing dinner for guests; GDS 5, deficit sufficient to interfere with independent community survival, with inability to recall major relevant aspects of current and past life during the clinical interview (eg, address or telephone number of many years or names of certain close family members, or the names of schools attended for years and from which the subjects may have graduated); GDS 6, deficits in daily life activities such as dressing and bathing, with general lack of awareness regarding recent events and life experiences and sketchy knowledge of personal history; and GDS 7, deficit sufficient to require assistance with toileting and feeding, with both urinary and fecal incontinence, with severely circumscribed or entirely absent verbal abilities, and, ultimately, with loss of ambulatory skills. The subject population consisted of 27 control subjects (GDS stages 1 or 2), 20 subjects with mild but objectively demonstrable impairment (GDS stage 3), and 88 subjects with moderate to very severe impairment from probable AD (GDS stages 4 through 7) (Table 1).

Established procedures were used for examination of deep tendon reflexes and plantar responses,[26] muscle tone (ie, paratonic rigidity), and release signs.[27] Four deep tendon reflexes (biceps, triceps, quadriceps, and gastrocnemius-soleus), as well as the plantar responses, presence of paratonic rigidity (also referred to as paratonia and defined as an irregular opposition of the musculature of the limb to passive manipulation), and eight release signs (sucking reflex [tactile and visual], hand and foot grasp, rooting, snout reflex, glabellar blink reflex, and palmomental reflex) were studied. The degree of activity of these reflexes was rated on a seven-point activity scale. On this scale, points 1, 3, 5, and 7 were well-defined points, while points 2, 4, and 6 were intermediate numerical scores, used in situations falling between the four well-defined points.

For the deep tendon reflexes, the criteria for increased activity were any or all of the following: amplitude, briskness, extent of stimulus zone within which a specific reflex could still be elicited, clonus, and/or occurrence of a spinal defense reflex, ie, mass response.[28] Briefly, a rating of 1 denoted a normal or hypoactive response; a rating of 3 indicated a notable increase in amplitude and/or briskness; a rating of 5 denoted a distinct increase in amplitude, briskness, and/or extent of stimulus zone; and a rating of 7 denoted a very prominent, exaggerated response with clonus and/or spread of the activity to neighboring joints or a mass response.

For the plantar response, a rating of 1 denoted plantar flexion of the big toe, a rating of 3 denoted an absence of either dorsiflexion or plantar flexion of the big toe, a rating of 5 indicated a distinct and tonic (unequivocal) dorsiflexion, and a rating of 7 denoted a dorsiflexion of the big toe with spreading of the toes and/or a spinal defense reflex.

Paratonic rigidity, defined as stiffening of a limb in response to contact with the examiner's hand and an involuntary resistance to passive changes in position and posture, was graded according to the amount of passive force necessary to elicit it. A rating of 1 denoted an absence of paratonic rigidity, whereas a rating of 7 indicated minimal passive force is required for elicitation of the sequence.

With respect to release signs, habituation, duration of response, and intensity were used as criteria for increased activity. A rating of 1 denoted absence of the sign, a rating of 7 indicated an absence of habituation with a persistent response to the repeatedly applied stimulus (more detailed descriptions of the rating methods used for each neurologic variable are available from E.H.F.).

For deep tendon reflexes, plantar response, and muscle tone (paratonic rigidity), an abnormal response in both upper and/or both lower extremities was registered as abnormal. Responses were usually symmetrical, but occasionally, slight asymmetrical responses occurred. In these instances, the higher scores were entered.

In addition to these 14 individual neurological measures, five summary measures, consisting of combinations of all or several measures, were studied. The four deep tendon reflexes were examined as a summary measure. Five individual release signs, namely, sucking (tactile and visual), grasping (hand and foot), and rooting, were combined in one variable called *prehensile release signs.* Three other release signs, namely, the snout reflex, the glabellar blink reflex, and the palmomental reflex, were also combined in one variable, called *nociceptive release signs.* Another summary measure included all of the release signs studied. The final summary measure combined data from the 14 individual measures.

Analysis Procedure

With regard to the activity rating of neurological observations, we examined the findings employing three different cut-offs, reflecting three levels of conservativeness for defining an observation as hyperactive. The least conservative cutoff required an activity rating of 3 or greater, the moderate cutoff a rating of 5 or greater, and the most conservative cutoff required a rating of 7, signifying the highest activity on the neurologic rating measure. This approach was taken so that the possible emergence of neurologic changes in the course of the dementia process could be more adequately assessed (ie, before, as well as after, they appear as unequivocal and prominent signs) and to describe the evolution of neurologic changes in AD using differing criterion variables.

RESULTS

Results were analyzed from two different perspectives: prevalence of hyperactive responses using the three different criteria defining increased activity noted above and the mean activity rating of responses with increasing severity of dementia as measured by GDS stage.

Prevalence of Hyperactive Responses

Figures 1 through 6 plot the percentages of subjects showing hyperactive responses across GDS stages for some of the key neurological variables, using the three different criteria for rating a test response as hyperactive. With the exception of the nociceptive release signs, there was a general trend for an increased prevalence of hyperactive responses with increasing severity of dementia. χ^2 Analyses were used to determine which of the cognitively impaired groups (GDS stages 3 through 7) evidenced a significantly higher prevalence of hyperactivity than did the normal elderly control subjects (GDS stages 1 and 2) for the key neurological variables. These χ^2 analyses were carried out separately for each of the three criteria for rating a response as hyperactive and are summarized in Table 2.

*GDS indicates Global Deterioration scale; NS, not significant ($P < .05$). GDS stages 3 through 7 refer to cognitively impaired subjects in comparison with control subjects (GDS stages 1 and 2). See "Measures" section for explanation of GDS stages.

When all 14 separate scores obtained on deep tendon reflexes, plantar responses, muscle tone, and release signs were combined and examined as one single summary variable (Fig 1), each of the subject groups from GDS stage 4 through stage 7 manifested a significantly higher prevalence than did the control subjects, when hyperactivity was defined either by a rating of 3 or greater or a rating of 5 or greater. When the most conservative criterion was employed (rating of 7), subjects with AD at GDS stages 5, 6, and 7 showed significantly higher prevalence rates than did the control subjects. Interestingly, using both less conservative criteria, significant differences in prevalence were also noted between the patients with only mild but objectively demonstrable cognitive impairment (GDS stage 3) and the control subjects.

Prevalence of hyperactive deep tendon reflexes increased with severity of dementia but only for an activity rating of 3 or greater and 5 or greater (Fig 2). Prevalence of an abnormal plantar response (ie, nonflexor response) was significantly associated with an increase in cognitive decline only for a rating of 3 or greater in the patients with late stages of AD (Fig 3). Prevalence of paratonic rigidity increased significantly with a decline in cognition for an intensity rating of 3 or greater in patients with GDS stages 5 and above, and for an intensity rating of 5 or greater in patients with GDS stages 6 and 7. Five release signs, eg, sucking (tactile and visual), grasping (hand and foot), and rooting, collectively labeled "prehensile release signs," showed the same prevalence pattern (Fig 5). They were absent in control subjects (GDS stages 1 and 2) and in mildly cognitively impaired subjects (GDS stage 3), as well as in subjects with GDS stages 4 and 5. Prevalence for this measure showed a steep increase in the GDS stage 6 and, especially, GDS stage 7 (Fig 5) as compared with control subjects.

Three release signs, ie, the snout reflex, glabellar blink reflex, and the palmomental reflex, collectively labeled "nociceptive release signs," showed an increased prevalence for mildly cognitively impaired subjects (GDS stage 3) and in patients with probable AD at GDS stages 4, 5, and 6, but less generally at GDS stage 7, as compared with control subjects (Fig 6). These release signs are not plotted individually, but they showed the following patterns: The snout reflex showed a noticeable increase from GDS stages 3 through 6, but declined again in GDS stage 7. The glabellar blink reflex and the palmomental reflex were occasionally observed in normal control subjects (GDS stages 1 and 2) and were more prominent in GDS stages 3 through 6 at an activity rating of 3 or greater and 5 or greater. Only one patient in GDS stage 7 had a glabellar blink reflex at an activity rating of 7, the most conservative rating.

Mean Severity of Hyperactive Responses

The data were also analyzed from the viewpoint of mean response activity across the GDS stages (Table 3). When the scores of all 14 neurologic measures (ie, deep tendon reflexes, plantar responses, muscle tone, and release signs) were combined in one summary variable, each of the AD groups (GDS stages 4 through 7), as well as the mildly cognitively impaired group (GDS stage 3), showed a significantly higher mean rating on this summary variable than did control subjects (GDS stages 1 and 2). With respect to deep tendon reflexes, each of the probable AD groups (GDS stages 4 through 7) showed a higher mean value than did control subjects. Patients with AD in GDS stages 5 through 7 had significantly higher mean scores on paratonic rigidity than did control subjects. Patients in each of these GDS stages also had higher mean scores on paratonic rigidity than did patients in the preceding GDS stage. With respect to the prehensile release signs, subjects in GDS stage 6 had significantly higher mean ratings for the hand grasp reflex and the foot grasp reflex compared with control subjects and compared with subjects in GDS stage 5. Subjects in GDS stage 7 had significantly higher mean ratings for the hand grasp and foot grasp reflexes as well as for the visual and tactile sucking reflexes and for the rooting reflex than did subjects in GDS stage 6.

A one-way analysis of variance and Newman-Keuls follow-up procedure for age showed that the control group (GDS stages 1 and 2) was significantly

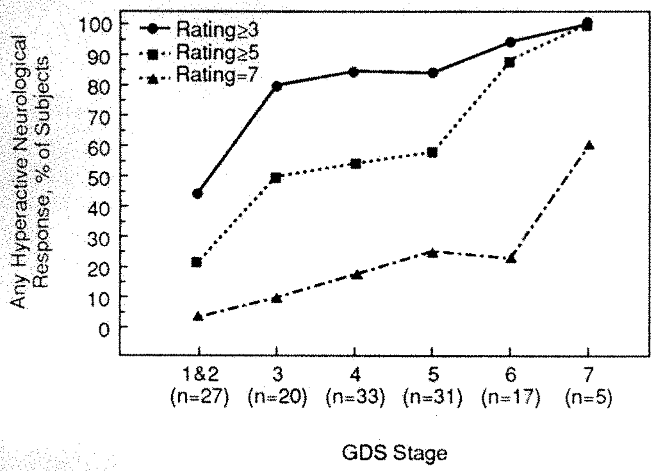

Fig 1.—Percentage of subjects showing any hyperactive neurological response studied (ie, any hyperactive deep tendon reflex, plantar response, muscle tone, or release sign) as a function of the Global Deterioration Scale (GDS) stage, using three different ratings of hyperactivity.

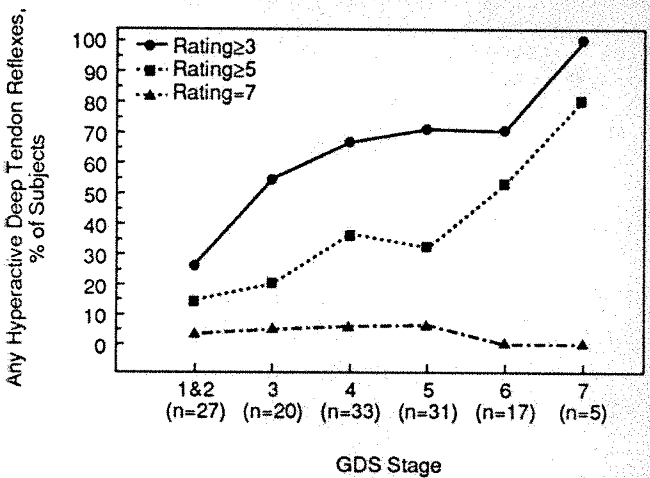

Fig 2.—Percentage of subjects showing any hyperactive deep tendon reflexes (ie, any biceps, triceps, quadriceps, or gastrocnemius-soleus reflex hyperactivity) as a function of the Global Deterioration Scale (GDS) stage, using three different ratings of hyperactivity.

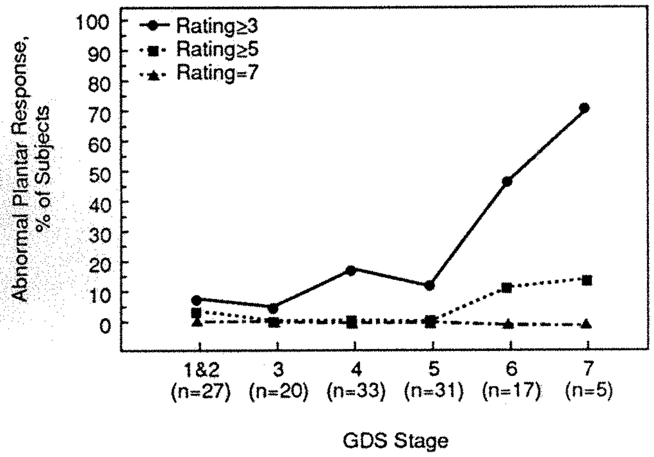

Fig 3.—Percentage of subjects showing an abnormal plantar response as a function of the Global Deterioration Scale (GDS) stage, using three different ratings of abnormality.

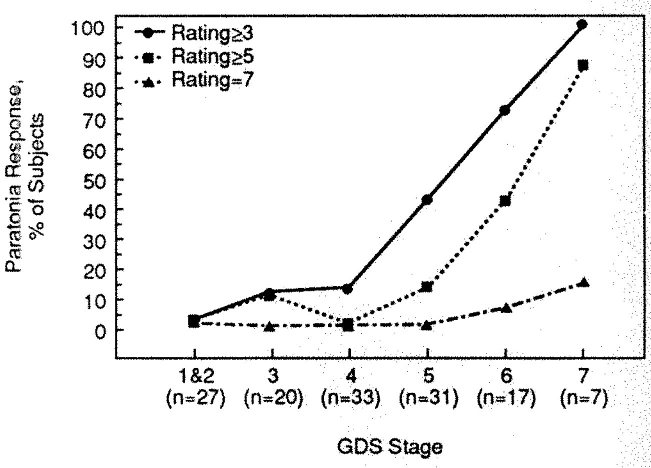

Fig 4.—Percentage of subjects showing paratonia as a function of the Global Deterioration Scale (GDS) stage, using three different ratings of activity.

Fig 5.—Percentage of subjects showing prehensile release signs as a function of the Global Deterioration Scale (GDS) stage, using three different ratings of activity.

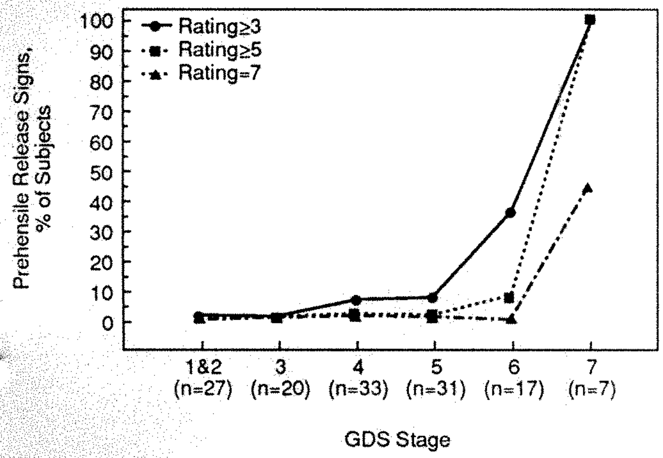

Fig 6.—Percentage of subjects showing nociceptive release signs as a function of the Global Deterioration Scale (GDS) stage, using three different ratings of activity.

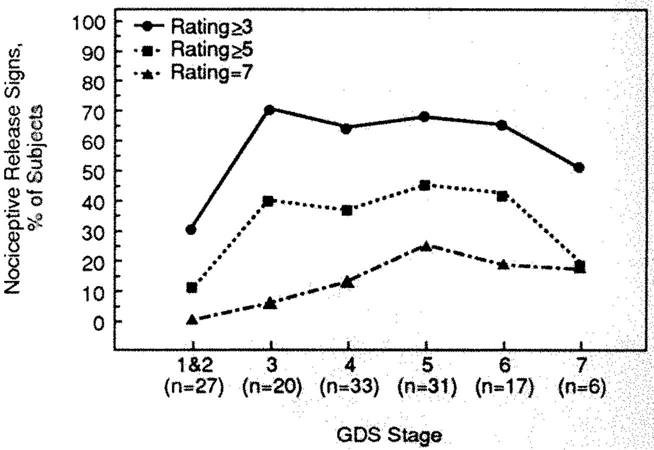

younger than the group with the most severe AD (GDS stage 7). Thus, we repeated the above analyses with a subset of the control subjects that were matched in age to the subjects with GDS stage 7. This analysis showed significantly higher mean activity ratings for 12 of the 14 individual neurological variables that showed such differences in Table 3 (biceps and quadriceps reflexes were the only exceptions). Therefore, age differences apparently do not account for the remaining between-group differences observed.

COMMENT

Alzheimer's disease is a slowly escalating neurodegenerative process, insidious in onset, and with extensive neuropathologic changes in the cerebral cortex and subcortical areas.

The classic neurologic examination, as it is commonly used by clinicians, is eminently suited to locate pathogenic factors, but it may not always be a sensitive enough technique for revealing the subtle changes occurring in AD, especially in the early stages. This problem might, to some extent, be addressed by rating the observed clinical signs on a scale and by looking for patterns in groups of individual signs as the illness evolves.

Subjects with the mildest degree of objectively demonstrable impairment (GDS stage 3) in our study did not show statistically significant changes in individual neurologic measures studied. However, they had significantly higher scores on a summary variable that combined the scores of all deep tendon reflexes, plantar responses, muscle tone, and release signs studied, suggesting subtle changes in neurologic function. They also obtained higher scores on deep tendon reflex activity prevalence as a summary measure and on the prevalence of a combination of nociceptive release signs (ie, snout reflex, glabellar blink reflex, and palmomental reflex), as compared with normally functioning healthy elderly control subjects. The prognosis with regard to clinical deterioration of subjects with mild memory impairment (GDS stage 3) is not yet entirely clear. This stage may herald dementia, but not necessarily only of the Alzheimer type.

The trend to increased prevalence of hyperactivity on the combined and individual deep tendon reflex variables studied continued throughout the GDS stages of progressive AD. Plantar responses that were commonly flexor in the early stages of probable AD became less distinctly flexor in the late GDS stages.

*Values are mean (± SD). GDS indicates Global Deterioration Scale; NS, not significant ($P > .05$). For explanation of GDS stages see "Measures" section.

†*P* values show significance of change in neurologic variable with GDS (F probability).

‡Significantly different from control subjects (GDS stages 1 and 2) at $P < .05$ (one-way analysis of variance using Newman-Keuls follow-up procedure).

§Significantly different from preceding GDS category at $P < .05$ (one-way analysis of variance using Newman-Keuls follow-up procedure).

A prominent pyramidal syndrome with very active deep tendon reflexes, clonus, and Babinski responses, however, was not seen in any of the GDS stages. Patients with GDS stage 7 frequently had prominent foot-grasp reflexes that presumably could obscure a Babinski response. Sometimes an extensor plantar response could be elicited in these patients by other techniques, such as the Oppenheim reflex or the Gordon reflex.

Release signs were common in all patients with probable AD (GDS stages 4 through 7), a finding also reported by Huff et al.[17] Commonly regarded as evidence of diffuse brain damage, their teleology is presently not clear.[29] The results of this study indicate that from the perspective of AD these signs seem to fall into two different categories. The prehensile release signs (sucking, grasping, and rooting) were associated with the severity of dementia only in the late stages of AD (GDS stages 6 and 7). These signs were not present in patients with early dementia. The grasp reflexes became more prominent in GDS stage 6. This was followed by prominent sucking reflexes and rooting reflexes in patients with GDS stage 7.

Paratonic rigidity, also referred to as paratonia or gegenhalten, is sometimes regarded as a release sign, and it is probably a constituent of the postural reflexes. Paratonia followed a prevalence pattern similar to the prehensile release signs with the exception that it was already prominent in GDS stage 5. All of the patients with GDS stage 7, who displayed all of the prehensile release signs and paratonia prominently, had also lost the ability to ambulate.

De Ajuriaguerra et al[30] have described a prehensile or grasping behavior in patients in the late stage of progressive dementia, following psychomotor disintegration. The authors observed a remarkable similarity between this stereotyped behavior and the oral type behavior of the neonate. They believed that the reemergence of this lower level of neuronal integration is related to the loss of cortical inhibitory function, in accordance with the postulate of Hughlings Jackson that the dissolution process roughly represents subsequent steps down the ontogenetic scale. Paulson and Gottlieb[12] observed simultaneous grasping, sucking, rooting, and muscle hypertonicity in patients with late-stage chronic diffuse brain disease of varying causes. Yakovlev[31] has described the evolution of a syndrome of paraplegia in flexion of cerebral origin, eg, a highly patterned sequence of change in posture observed in the course of mental deterioration in individuals suffering from a severe degenerative cerebral disease. Initially, there was paratonic rigidity on a background of impaired intellectual function, with exaggerated tendon reflexes and Babinski's signs, followed by the gradual evolution of stereotyped behavior with rigidity of posture, spontaneous grasping, and sucking. The end stage was that of profound dementia with pelvicrural flexion contracture, without sensory loss, and, usually, without pyramidal tract signs and with foot-grasp reflexes. Individual hyperactive muscle stretch reflexes were commonly replaced by a mass reflex, as occurs in the fetus. In patients with probable AD, the prehensile signs, with inclusion of paratonia, might presumably be parts of a gradually evolving prehensile syndrome, as described by de Ajuriaguerra et al, and, eventually, of paraplegia in flexion, as Yakovlev has described.

A second group of release signs, namely, snout reflex, glabellar blink reflex, and palmomental reflex, was collectively labeled nociceptive because they each constitute the contraction of one facial muscle in response to a perceived threatening or noxious stimulus. They are probably also closely related to nociceptive skin reflexes.[32] In the present study, these nociceptive signs as a group were less distinctly associated with dementia progression. These signs occurred much earlier in the course of cognitive decline than did the prehensile signs. The prevalence of these signs was generally lower in late-stage dementia (GDS stage 7) as compared with the early and middle stages (GDS stages 4 through 6), and even with the stage of mild memory impairment (GDS stage 3). Observation of these signs in late-stage AD could be obscured by increased presence of sucking, blepharospasm, and facial dyskinesia, which are more common in late-stage AD. Interestingly, these signs are also frequently seen in patients with Parkinson's disease,[33-36] in whom they reverse after levodopa therapy,[36,37] as well as in patients with tardive dyskinesia,[38] dystonic disorders,[39] and human immunodeficiency virus encephalopathy.[40] Habituation of the blink reflex is associated with mature dopaminergic brain circuits.[41] Prominent presence of these signs in AD may be indicative of a subgroup with parkinsonian features and may have implications with regard to the desirability of the use of psychotropic agents, with prominent extrapyramidal side effects, widely prescribed to control the agitation and other behavioral disturbances commonly occurring in AD.

Release signs and pyramidal signs have been reported to predominate in vascular dementia with lacunae, especially in the frontal lobes.[42] Patients with evidence of such lesions on computed tomographic scan or magnetic resonance imaging were excluded from our study. Some of the patients in our study had evidence of periventricular white matter hypodense areas on computed tomographic scan or magnetic resonance imaging, as described by Brun and Englund.[43] Increased impairment of gait has been reported to appear in patients with AD showing these white matter changes, but not in cognitively intact elderly subjects with similar lesions.[44] Whether this particular change had any influence on the occurrence of release signs and pyramidal signs in the subjects of our study requires further investigation.

The finding of subtle neurologic change in mildly cognitively impaired, but not demented, subjects is interesting. Whether it has any consequences for predicting further cognitive deterioration needs to be elucidated.

Some reservation with regard to the present findings is warranted. This is a cross-sectional study. Only a longitudinal study, which is currently in progress, will be able to confirm if the above observed sequence of neurologic changes is characteristic of AD.

Also, the number of subjects in this study was relatively small. We hope to publish a future study with more subjects. The specificity of the above-reported observations with respect to probable AD compared with other forms of dementia also needs further investigation.

We believe, however, that the observations made in this study justify further investigation to determine the usefulness of quantitative measurements of cognition-independent neurologic signs as independent markers of early cognitive impairment and clinical severity of dementia in AD and, perhaps, as indicators for the effectiveness of putative therapeutic agents in the treatment of AD.

This study was supported in part by the US Department of Health and Human Services grants AG-03051, MH-35976, and P50 MH44386.

The methodology described herein is the subject of a proposed United States patent application.

The authors would like to gratefully acknowledge Jacob Cohen, PhD, Department of Psychology, New York University, NY, for statistical consultation.

Age at Onset of Alzheimer's Disease

Relation to Language Dysfunction

Kathryn A. Bayles, PhD

• A later age at onset of Alzheimer's disease (AD) was found to be related to diminished language performance in 86 patients with probable AD. A hierarchical linear model was constructed to assess effects of age at onset and disease duration on the performance of patients with AD on four language tasks (naming, reading, auditory comprehension, and writing to dictation) after controlling for disease severity. Results of univariate analysis, in which the dependent variable was the averaged language task performances, revealed a significant effect for age at onset of AD, but not for disease duration. To assess the possibility that the relationship between the age at onset of AD and language performance reflects effects of normal aging, the language tasks were given to 33 normal subjects of similar ages who scored perfectly on dementia severity measures. A convincing relationship was not found between test score and age.

(*Arch Neurol.* 1991;48:155-159)

Reports of heterogeneity in the neurobehavioral deficits in patients with Alzheimer's disease (AD) suggest the existence of clinical subgroups. One possible subgroup comprises individuals with an early onset of AD who have been reported to have language deficits more than would patients with late onset.[1-4]

Seltzer and Sherwin[1] classified 65 patients with AD as normal or abnormal in language function by performance on tasks modified from the Boston Diagnostic Aphasia Examination.[5] Proportionately more individuals with early age at onset of AD were present in the linguistically abnormal group than were in the linguistically normal group. Faber-Langendoen and colleagues[2] observed aphasic subjects with AD to be younger at onset of dementia than their nonaphasic counterparts. Filley et al,[3] who also administered portions of the Boston Diagnostic Aphasia Examination to patients with AD with early and late onset, reported greater language disorder in patients with early onset, but not as measured by the Boston Diagnostic Aphasia Examination subtests. Age-at-onset effects were apparent only on the Reitan-Indiana Aphasia Screening Test.[6] Using performance on the eight language-related items in the Mini-Mental State Examination (MMSE)[7] to detect aphasia, Chui and colleagues[4] reported 60% of their 146 patients with AD to be aphasic and the proportion of early-onset cases to be higher in the aphasic group compared with that in the nonaphasic group.

Reports of greater language impairment in patients with an early onset of AD have been challenged. Selnes et al[8] and Grady et al[9] failed to find a significant relationship between age at onset of AD and language deficit, and Cummings and colleagues[10] report language impairment in all their patients with AD that is proportional to severity of dementia.

Regardless of whether the aforementioned investigators found a relationship between age at onset of AD and language performance, none of them employed methodology whereby each subject's language score(s) was controlled for the effect of dementia severity, a necessary control because of the well-documented relationship between dementia severity and language score.[6,8,10,11] Such control subjects were employed in a large study of the effects of AD on language function. The purpose of this report is to present evidence that when effects of dementia are controlled, age at onset is related to degree of language deficit in such a way that the older the age at onset, the greater the degree of language impairment.

SUBJECTS AND METHODS

Subjects

Eighty-six individuals diagnosed with probable AD according to National Institute of Neurological and Communicative Disorders and Stroke-Alzheimer's Disease and Related Disease Association task force criteria[12] and 42 normal elderly control subjects participated in the study. Patients with probable AD had a history of progressive mental deterioration, including deficits in memory and at least one additional cognitive function. Subjects underwent thorough physical and neurological examinations performed by an experienced neurologist, independent neurobehavioral assessment, and standard laboratory testing. Excluded from the study were individuals who, by history, examination, or laboratory study, demonstrated a systemic or other

Table 1.—Characteristics of Patients With Alzheimer's Disease (AD) and Normal Elderly Subjects*

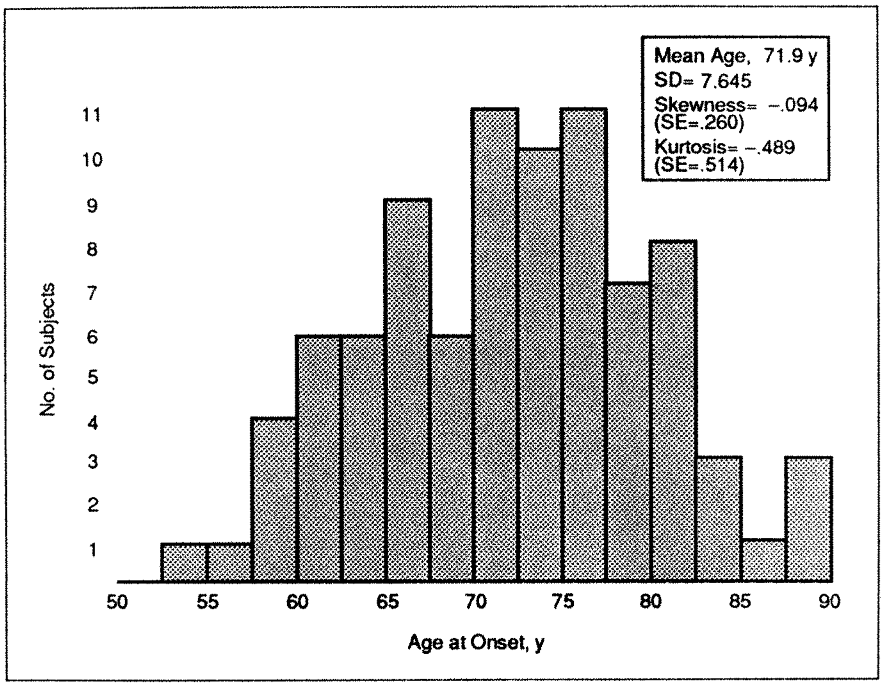
	Patients With AD/Normal Subjects			
Variable	**Mean**	**SD**	**Minimum**	**Maximum**
Age, y	76.59/73.40	7.56/7.59	58.18/61.57	94.51/93.49
Education, y	13.06/14.55	3.19/3.16	4.00/8.00	22.00/21.00
Estimated IQ	110.89/113.11	7.63/7.53	93.39/99.72	132.40/132.00

*The AD group (n = 86) consisted of 32 males and 54 females; the normal group (n = 42) consisted of 10 males and 32 females.

Table 2.—Questionnaire About the Presence of 25 Symptoms of Alzheimer's Disease

Which of the following symptoms have you noticed and when?

1. Complaints of memory problems
2. Problems in concentrating
3. Decreased knowledge of current or recent events
4. Forgetting information about his/her own personal history
5. Decreased ability to travel
6. Decreased ability to handle finances
7. Denies problems
8. Inability to perform complex tasks
9. Withdrawal from challenging situations
10. Forgetting where familiar objects were placed
11. Forgetting names formerly known well
12. Being lost or confused when traveling to familiar places
13. Coworkers aware of problem performing
14. Word- and name-finding problems apparent
15. Reading, but not retaining, information
16. Losing or misplacing objects of value
17. Sleep disturbance
18. Largely unaware of all recent experiences in his/her life
19. Difficulty remembering names of close family members
20. Unaware of his/her surroundings or environment
21. Incontinence
22. Change in personality
23. Change in mood (depressed, agitated, etc)
24. Movement problems
25. Fatigue



The distribution and range of perceived age at onset of Alzheimer's disease.

central nervous system disease associated with intellectual deterioration. Also excluded were individuals with a score of 4 or more on the modified Hachinski Ischemic Scale[13,14] and 12 or more on the Hamilton Depression Rating Scale.[15] Dementia severity was determined by score on the Global Deterioration Scale (GDS)[16] and answers to the questions from the MMSE[7] related to place, time, and the ability to copy.

In addition to the aforementioned exclusionary criteria, the patients with probable AD and normal control subjects had to meet the following inclusionary criteria: pass a speech discrimination test with 80% or better accuracy (see Bayles et al[17] for description), be literate and able to read newsprint, speak English as a first language, have no history of drug or alcohol abuse, and have normal intelligence as estimated by a regression equation using demographic information.[18] The demographic characteristics of study participants are shown in Table 1.

Perceived Age at Onset

Perceived age at onset of AD was specified by primary caregivers after reviewing with the examiner the neurobehavioral features of the disease and their patients' social and medical histories. Before the examiner reviewed the behavioral symptoms of the disease, the caregiver informants were asked to specify the first four symptoms that they observed and the approximate date of their appearance. Subsequently, they were questioned about the presence of 25 symptoms of the disease (Table 2), and asked to specify the time of appearance of those observed in the patient.

The date of the first report of memory impairment was used as the time of onset that was subtracted from the patient's age at testing to obtain perceived age at onset of AD, the datum used in study analyses (mention must be made of the fact that it is impossible to verify caregivers' reports of symptoms). The distribution and range of perceived age at onset of AD are presented in the Figure. Because this distribution is evidently continuous and unimodal (and apparently normal), age at onset is not dichotomized into early and late subgroups.

Duration of dementia was calculated by subtracting the date of onset from the date of testing. The mean disease duration for patients with AD was 4.67 years (SD = 2.37 years).

Tasks

The linguistic communication tasks administered in this study included confrontation naming, auditory comprehension, writing to dictation, and reading comprehension. The tasks, which used the same stimuli, were administered in the order listed herein. In the confrontation naming, task subjects were asked to name 13 black-and-white line drawings presented individually. The objective of the auditory comprehension task was to select, from among four, the correct colored photograph of the object named by the examiner. In the dictation task, the examiner read each word aloud and the subject was required to write the words on a sheet of paper. In the reading comprehension task, the subject had to read the printed name of an object and select the photograph of the object *from* among four photographs of objects.

Table 3.—Effect of Disease Duration and Age at Onset of Disease on Average Language Performance After Controlling for Disease Severity*

Source of Variation	Sum of Squares	*df*	Mean Square	F	*P*
Constant	6628.20	1	6628.20	1941.43	.000

*Jonckheere's test for negative trend over scores of 11 through 13 was not statistically significant ($z = 1.29$, $P = .10$).

†Welch's approximate t test between scores of 12 and 13 was not statistically significant, $t(4.27) = .64$; two-sided $P = .276$.

‡Jonckheere's test for negative trend over scores of 11 through 13 was not statistically significant ($z = -.27$, $P = .61$).

RESULTS

A general linear model was constructed to assess the extent to which disease severity, disease duration, and age at onset of AD predict language performance. Severity variables comprised GDS, MMSE place questions, MMSE time questions, and the MMSE figure copy task. The model was hierarchical, ie, each term in the model was tested after controlling for the terms that preceded it. By considering the severity variables first, it was possible to assess the effects of disease duration and age at onset on language performance after controlling for disease severity.

Initially, the effects of all possible terms on language performance were considered; eventually, nonsignificant terms were removed from the model (eg, subjects' scores on the five orientation questions about time) to make it as parsimonious as possible. This model was employed in a univariate analysis, in which the dependent variable was the average performance on the four Arizona language tasks, and a multivariate analysis, in which the dependent variables were the separate performances on the four tasks.

Univariate Analysis

Results of univariate analysis, presented in Table 3, revealed several interesting facts about the measurement of disease severity in relationship to language performance. First, the simple task of copying a figure yields significant information about language performance even after controlling for GDS score and performance on MMSE place orientation questions. Second, after controlling for GDS score and place orientation questions, time orientation questions yield no significant information. Third, although the GDS score is based on observation of myriad patient characteristics, MMSE place orientation questions alone turn out to be more informative. Together these terms account for a sum of squares of 212.65 and if the effect of GDS is removed first from this total, MMSE place orientation questions additionally account for 103.10 (48.5%). However, if orientation to place is considered first, it alone is able to account for 200.63 (94.3%), nearly all of the variation attributed to both measures.

With respect to the variables of interest in this study, it is evident that any effect of disease duration on language performance is entirely accounted for by the objective measures of disease severity. On the other hand, even after controlling for disease severity, it appears that age at onset of AD is significantly related to language performance. Moreover, inspection of the model coefficients revealed that *later* onset is associated with diminished performance, the reverse of what many authors have reported.[1-4]

Because F tests are often sensitive to nonnormality and heteroscedasticity, it was deemed advisable to verify the above relationship by a more robust procedure. Accordingly, age at onset of AD was removed from the model. The residuals from this restricted model represent each subject's language score after adjusting for dementia severity. These adjusted language scores were then nonparametrically correlated with age at onset, and the same relationship was observed (Kendall's $\tau = -.1639$, $P = .025$).

Multivariate Analysis

More detailed insight into the relationship between age at onset of AD and language performance may be gained from the multivariate analysis. The effect of age at onset of AD on each of the four language variables is reported in Table 4. It becomes apparent that age at onset is negatively associated with performance on the confrontation naming, auditory comprehension, and reading comprehension tasks, but it is unassociated with performance on the dictation task.

Effects of Normal Aging

The above analyses demonstrate a relationship between age at onset of AD and language performance for subjects with AD. However, it is important to emphasize that age at onset is highly correlated with age at testing ($r = .9516$), an association that raises the possibility that the relationship observed between age at onset and language performance is due to the effects of normal aging. Certainly, the variables employed to quantify severity of dementia can be expected to have removed the (presumably gross) effects of normal aging on subjects with AD, but it is, nonetheless, conceivable that a language-specific component to the aging process still remains. It would be satisfying if the issue of the possibility of residual aging effects on the language performance of the subjects with AD could be resolved by introducing age at testing into the hierarchical general linear model previously employed. Unfortunately, the high correlation between age at testing and age at onset in subjects with AD precludes such a solution; this is known as the problem of multicollinearity in linear models. Therefore, an assessment of the residual effects of normal aging must be based on the distribution of language scores of normal subjects.

One method of assessment would be to apply the same general linear modeling procedure to data from normal subjects. If, after controlling for the effects of the severity variables, age at testing was not a significant predictor of language performance, it could be concluded that the effects of normal aging were removed by the severity variables. It would then follow that the age-at-onset effect detected in subjects with AD was something distinct from normal aging. However, only nine of the 42 normal subjects exhibited deficits in any of the severity variables and, thus, there was insufficient variability in the severity variables to adequately test the model. Nevertheless, severity can be controlled by taking a single group of normal subjects who are all at the same level of severity and examining the relationship between age at testing and language performance within that group. Only one such group existed, namely, the group of 33 subjects with no severity deficits. Table 5 contains the data regarding these subjects and demonstrates how age at testing varied with language performance for them. Notice that the data fail to convincingly support the argument that performance on these four simple tasks declines with normal aging. Nonetheless, that possibility cannot be completely discounted.

COMMENT

Early age at onset of AD, as specified by caregivers, was not found to be related to greater language impairment in a large sample of subjects with AD for whom severity of dementia was controlled. Rather, a subtle, but robust, relationship was found between later age at onset of AD and greater language impairment. Analysis of performance on the individual tasks indicated the presence of this relationship for confrontation naming and auditory and reading comprehension, but not for writing to dictation. Disease effects on writing to dictation may be less severe, because the task is mechanical, cognitively less effortful, and, possibly, can be completed without involvement of semantic (conceptual) memory.

The high correlation between age at onset and age at testing raised the possibility that this relationship was due to the effect of normal aging. This possibility was explored by examining the effect of age at testing on language performance of normal subjects. When the average age at testing for each language score was reviewed, no convincing relationship was observed.

Results of the present study may differ from those of investigators[1-4] reporting a relationship between early disease onset and more prominent language deficits, because the language performance scores of individual participants in this study were controlled for dementia severity. In the Seltzer and Sherwin study,[1] severity of dementia was controlled by testing limited to those individuals who retained "a sufficient level of general intellectual function to engage in testing"[1,p145] and by controlling the early- and late-onset groups for disease duration. Disease duration may not accurately measure degree of dementia severity in view of the reports[2,19-21] that some patients with AD have a rapidly progressing disease, whereas others have a slowly progressing disease.

The report by Filley et al[3] that their early-onset group had greater language impairment was based on the results of performance on seven language measures. Yet, on only one of the seven language measures was the early-onset group significantly more impaired. Further, although the authors reported a trend toward greater impairment by early onset in the word discrimination and complex ideational material subtests of the Boston Diagnostic Aphasia Examination, the mean scores of the early- and late-onset groups on these tasks were extremely close (early-onset group mean for word discrimination was 68.62, and late-onset group mean was 68.00; early-onset group mean for complex ideational material was 8.81, and late-onset group mean was 9.18) and the associated probability values were $P = .73$ in both cases. The single test for which a significantly greater impairment was observed in the patients with early onset of AD was the Reitan-Indiana Aphasia Screening Test.[6] However, no information was given about the test and the number of false-positive results typically associated with it. Finally, patients in the early-onset group may have been premorbidly less gifted in language and general intellectual ability than those in the late-onset group. Indeed, they were scored lower in full-scale, verbal, and performance IQ than were patients in the late-onset group. Although only the differences in full-scale and verbal IQ were significantly different, the pattern was the same for all three measures.

Chui and colleagues[4] used eight items from an MMSE and clinical observation of paraphasias, word-finding difficulty, or reduction in speech output to define language deficit. No information was provided as to what constituted significant numbers of paraphasic errors or word-finding difficulty. Sixty percent of the patients with AD were designated as aphasic, but these individuals were also more severely demented. Indeed, the authors reported that "presence and severity of aphasia were significantly associated with greater severity on the GDS ($t = 6.7$, $P < .0001$)."[4,p1546] Thus, the poorer language performance by the aphasic patients may simply reflect more severe dementia.

Faber-Langendoen et al[2] used performance on a brief clinical aphasia battery to dichotomize their group of 150 subjects with AD into aphasic and nonaphasic subgroups. Thereafter, the authors calculated the mean age at onset of AD for each group and reported that the mean age for the aphasic group was significantly lower. However, the difference in mean ages was only 2.8 years.

The results of the present study

were harmonious with those of Selnes et al,[8] although the question can be asked why these investigators did not report a relationship between later age at onset and greater language impairment. Perhaps the reason was that Selnes and colleagues used the MMSE scores, which are heavily dependent on language performance, for controlling dementia severity in their groups with early and late age at onset of AD.

Grady and colleagues,[9] who also failed to find a relationship between early age at onset and greater language impairment, did not control the effects of dementia severity on language performance on a subject-by-subject basis and perhaps, therefore, failed to detect the subtle relationship between later age at onset and greater language impairment reported in the present study. The variability within the early- and late-onset groups in the Grady study may have been enough to mask this subtle effect.

In summary, a relationship between early age at onset of AD and greater language impairment was not confirmed by results of this study. Rather, a subtle, but statistically significant, relationship was observed between a later age at onset of AD and greater language impairment. The procedure of controlling for the effects of dementia severity on language performance scores on a subject-by-subject basis likely accounts for the principal differences between this study and those of other investigators.

This study was supported by National Institute of Mental Health grant MH40827 and Biomedical Research grant 829023.

The author acknowledges Dr Michael Trosset, statistician, for his assistance in the statistical analyses and Cheryl Tomoeda, MS, for her help in subject testing and preparation of the manuscript.

• Three pairs of twins, each with proved monozygosity, were shown to be discordant for dementia of the Alzheimer's type and to have remained discordant for periods of 8 to 11 years. Dementia of the Alzheimer's type was demonstrated by history; serial clinical examinations; serial measurements of cerebral glucose utilization using positron emission tomography and of cerebral ventricular volumes and of rates of change of volumes using quantitative computed tomography; and by serial neuropsychological tests. The results of each of these measures showed no evidence of clinical abnormality in any unaffected twin. DNA markers from the proximal long arm of chromosome 21 did not distinguish between the affected and the unaffected member of any pair of identical twins. Family pedigrees were negative for Alzheimer's disease. The results suggest that environmental or other nongenetic factors contribute to Alzheimer's disease in discordant monozygotic twins, or that some cases arise by a postzygotic somatic mutation.

(*Arch Neurol.* 1991;48:160-168)

Alzheimer's disease is a progressive neurodegenerative disorder that is the most common cause of dementia in the United States, but its precise cause is unknown. It affects about 5% of individuals older than 65 years and 10% to 15% of those older than 80 years of age.[1] Established risk factors are age and familial aggregation. An autosomal dominant mode of transmission with a lifetime (90-year) risk of 50% among first-degree relatives of probands has been reported.[2,3] Reports of Alzheimer's disease in twins suggest a 40% to 50% concordance for the disease in monozygotic twins and an 8% to 50% concordance in dizygotic twins.[4-18]

Of these reports, only two[6,13] describe twins discordant for dementia of the Alzheimer's type (DAT) with proved monozygosity and with neuropathological proof of Alzheimer's disease in the affected twin. No report provides detailed proof of discordance in proved monozygotic twins, using studies of brain anatomy and metabolism with computed tomography (CT) and positron emission tomography (PET), respectively, and a complete battery of cognitive tests. Furthermore, no study of monozygotic twins discordant for DAT has been longitudinal in nature. However, as age at onset of DAT may differ by up to 11 years between twins with documented monozygosity who eventually become concordant,[15] a finding of discordance in a single cross-sectional analysis may be of limited value for estimating the true discordance rate, or even for establishing discordance in a given pair of monozygotic twins.[9,19] We, therefore, thought it important to further examine the discordance of Alzheimer's disease in monozygotic twins. To do this, we document, in a longitudinal experimental design, differences in brain metabolism, cognitive function, and neuroanatomy in three pairs of monozygotic twins thought to be discordant for DAT and provide neuropathological confirmation of Alzheimer's disease in one of the affected twins. By evaluating social and medical histories, as well as environmental exposure of each of the twins, and by examining DNA markers from chromosome 21,[20,21] we try to distinguish an environmental or genetic factor that might contribute to Alzheimer's disease. Finally, because of the approximately 40% concordance rate of DAT in monozygotic twins,[14] we thought it possible, using sensitive measures of brain function and anatomy, that one of the unaffected twins from the three twin pairs might show early, preclinical changes of DAT. Our results have been partially reported in abstract form.[22]

SUBJECTS AND METHODS

Subjects

Our subjects were two male twin pairs, 1A* and 1B and 2A* and 2B; and one female twin pair, 3A* and 3B. Asterisk denotes the twin with a diagnosis of DAT, probable

Alzheimer's disease, using the National Institute of Neurological and Communicative Disorders and Stroke-Alzheimer's Disease and Related Diseases Association criteria.[23] The twins 1A* and 1B were described partially by Luxenberg et al[24] and had been identified from the Twin Registry of the National Academy of Sciences, National Research Council (see the acknowledgments).[25] Each subject signed an informed consent to participate in the study.

Detailed histories were obtained for each subject. Each twin also underwent comprehensive physical and neurologic examinations, and the following tests were performed: electrocardiogram, a chest roentgenogram, CT of the head, an electroencephalogram, and routine laboratory tests, including complete blood cell count, differential white blood cell count, VDRL test, and measurements of blood levels of urea, as well as creatinine, antinuclear antibody, vitamin B_{12}, folate, and thyroid hormone levels. Each twin underwent PET, quantitative CT, and extensive cognitive testing, as described below. Depending on compliance, the procedures were repeated one to three times over periods of up to 3 years.

Age-matched volunteers were used as control subjects. They were screened rigorously for medical or neurological illness, and met stringent health criteria as previously described.[26] Different control groups were used for each of the neuropsychological, PET, and CT studies. For cross-sectional CT studies, there were 25 male control subjects with a mean age (±SD) of 61 ± 6 years, and 19 female control subjects with a mean age (±SD) of 60 ± 6 years. For longitudinal CT studies, male (n = 7) mean age (±SD) was 61 ± 6 years, and female (n = 4) mean age (±SD) was 58 ± 5 years. For the PET control subjects, using the ECAT II scanner (ORTEC, Life Sciences, Oak Ridge, Tenn), male (n = 18) mean age was 60 ± 3 years and female (n = 6) mean age was 62 ± 3 years, and using the Scanditronix (Uppsala, Sweden) scanner, male (n = 8) mean age was 59 ± 4 years and female (n = 22) mean age was 62 ± 6 years. Control subjects for the neuropsychological tests are described below.

Procedures

PET.—Each subject underwent PET using ^{18}F-2-fluoro-2-deoxy-D-glucose to determine regional cerebral metabolic rates for glucose ($rCMR_{glc}$). The procedure was carried out in the early part of the study, using an ECAT II tomograph (ORTEC) with in-plane and axial resolutions of 17 mm. Beginning May 1986, a more sensitive PC 1024 PET tomograph (Scanditronix) was employed, with an in-plane resolution of 6 mm and an axial resolution of 10 mm.

A subject was kept drug free for at least 2 weeks prior to a scan, refrained from alcohol, caffeine, and nicotine use for at least 24 hours, and fasted for 2 hours prior to the scan. The scan was performed with the subject supine in a quiet room, his eyes covered, and his ears plugged with cotton. Details of PET scanning on both machines have been presented elsewhere.[26-30]

The $rCMR_{glc}$ was calculated in milligrams of glucose consumed per 100 g of brain per minute ($mg \cdot 100\ g^{-1} \cdot min^{-1}$). We also calculated normalized metabolic ratios, defined as $rCMR_{glc}/CMR_{glc}$, where CMR_{glc} is the mean of $rCMR_{glc}$ in corticocerebral gray matter regions, as well as metabolic asymmetry indexes using the following equation:

$$\text{Asymmetry Index}\ (\%) = \frac{R - L}{(R + L)/2} \times 100$$

where R stands for $rCMR_{glc}$ in a right-sided region and L stands for $rCMR_{glc}$ in the homologous region in the left hemisphere.[27,29]

CT Scanning.—Noncontrast CT imaging of the brain was performed with an 8800 CT/T scanner (General Electric Corp, Milwaukee, Wis), for which full width at half maximum equaled 1 mm. Images were obtained parallel to the externally defined inferior orbitomeatal line and were analyzed quantitatively as described previously[31] to obtain volumes (cubic centimeters) for the third and lateral ventricles. Rates of change of ventricular volumes ($cm^3 \cdot y^{-1}$) were calculated from slopes of plots of ventricular volumes against time.

Neuropsychological Testing.—Overall dementia severity was measured using the Mattis Dementia Scale[32] and the full-scale IQ from the Wechsler Adult Intelligence Scale (WAIS).[33] Memory was evaluated with tests of immediate and delayed recall for stories and figures from the Wechsler Memory Scale.[34,35] Ability to maintain attention to complex or shifting sets, and planning ability, were evaluated with the Stroop Color Word Test,[36] the Trailmaking Test,[37] and the Porteus Maze Test.[38] Measures of language were the Verbal Comprehension and Memory and Distractibility Deviation Quotients from the WAIS,[39] a test of comprehension of syntactic relations in single sentences, and a test of serial naming (Controlled Word Association).[40] Measures of visuospatial construction were the WAIS Perceptual Organization Deviation Quotient, a test of the ability to copy geometric features of varying complexity (Extended Range Drawing),[29] and a test of three-dimensional block construction (Hiskey-Nebraska Block Patterns).[41]

For twin pair 1, the control sample was 10 subjects (5 men and 5 women) with a mean age (±SD) of 62 ± 8 years, and a mean education (±SD) of 13 ± 1 years. For twin pair 2, the control sample consisted of 38 men with a mean age of 64 ± 8 years and a mean education of 17 ± 2 years. For twin pair 3, the control sample was 13 women with a mean age of 63 ± 5 years and mean education of 13 ± 1 years. Thus, control subjects for twin pairs 2 and 3 were matched for age, sex, and education, but control subjects for twin pair 1 were not all male and were more educated than the twins.

Molecular Genetic Studies.—The physical structure of the portion of the proximal arm of chromosome 21, which has been suggested to harbor the familial Alzheimer's disease locus,[20,21] was assessed for postzygotic microdeletions or duplications that might discriminate affected from unaffected twins. Equivalent quantities of genomic DNA prepared from buffy coat leukocytes were digested to completion with the restriction enzymes *Eco*RI and *Hin*dIII. The resultant restriction fragments were resolved according to size by horizontal agarose gel electrophoresis and were transferred to nylon membranes by Southern blotting. Radiolabeled probes for the proximal chromosome 21 marker loci D21S11 (pPW236B), D21S52 (pPW511-1H), and D21S13 (pGSM21) then were hybridized to the genomic DNA on the nylon filter supports. The pattern of *Eco*RI and *Hin*dIII sites around these loci was deduced from the size and number of bands on the resultant autoradiogram, and were compared both between affected and unaffected twins, and with the known normal restriction patterns for these enzymes at these loci. At the D21S52 locus, the probe pPW511-1H reveals a restriction fragment length polymorphism with the enzyme *Hin*dIII. In individuals heterozygous for this restriction fragment length polymorphism, the signal from each copy of chromosome 21 can be resolved, and the intensity of the signal contributed by each chromosome can be compared to discover evidence of microduplications.[42] Two twin pairs (3A* and 3B; 2A* and 2B) each were polymorphic for this restriction fragment length polymorphism, having two alleles in each of the twins.

Statistical Analysis.—*Z* scores were used to decide if a particular value in a subject was significantly different from the control mean. A significant *Z* score was defined as 2 SDs above or below the control mean, equivalent to a level of significance of $P < .05$.[43] Mean values (±SD) are presented for control data.

RESULTS

Case Histories and Neuropathology

Twin Pair 1.—The twins 1A* and 1B, born in November 1925 are white men who were raised in rural Arkansas and attended school to the 11th grade. Both worked on a farm for more than 8 years, prior to the age of 30 years, where they were exposed to pesticides handled without gloves or masks. Both then worked in the construction business.

Medical History and Examination.—The twins were born at full-term by uneventful vaginal deliveries, 1A* being born first, and both had uneventful childhoods. Family history for DAT was negative (Fig 1, twin pair 1). In 1978, 1A* evinced personality changes with jealousy and paranoia and lost concern for safety while at work. Memory impairment became obvious in 1980. His medical history includes smoking one to two packs of cigarettes daily for over three decades and exposure to pesticides. His Mini-Mental State Examination (MMSE) scores[44] were 2, 2, and 1 in July 1985, February 1986, and January 1987, respectively, indicative of severe demen-

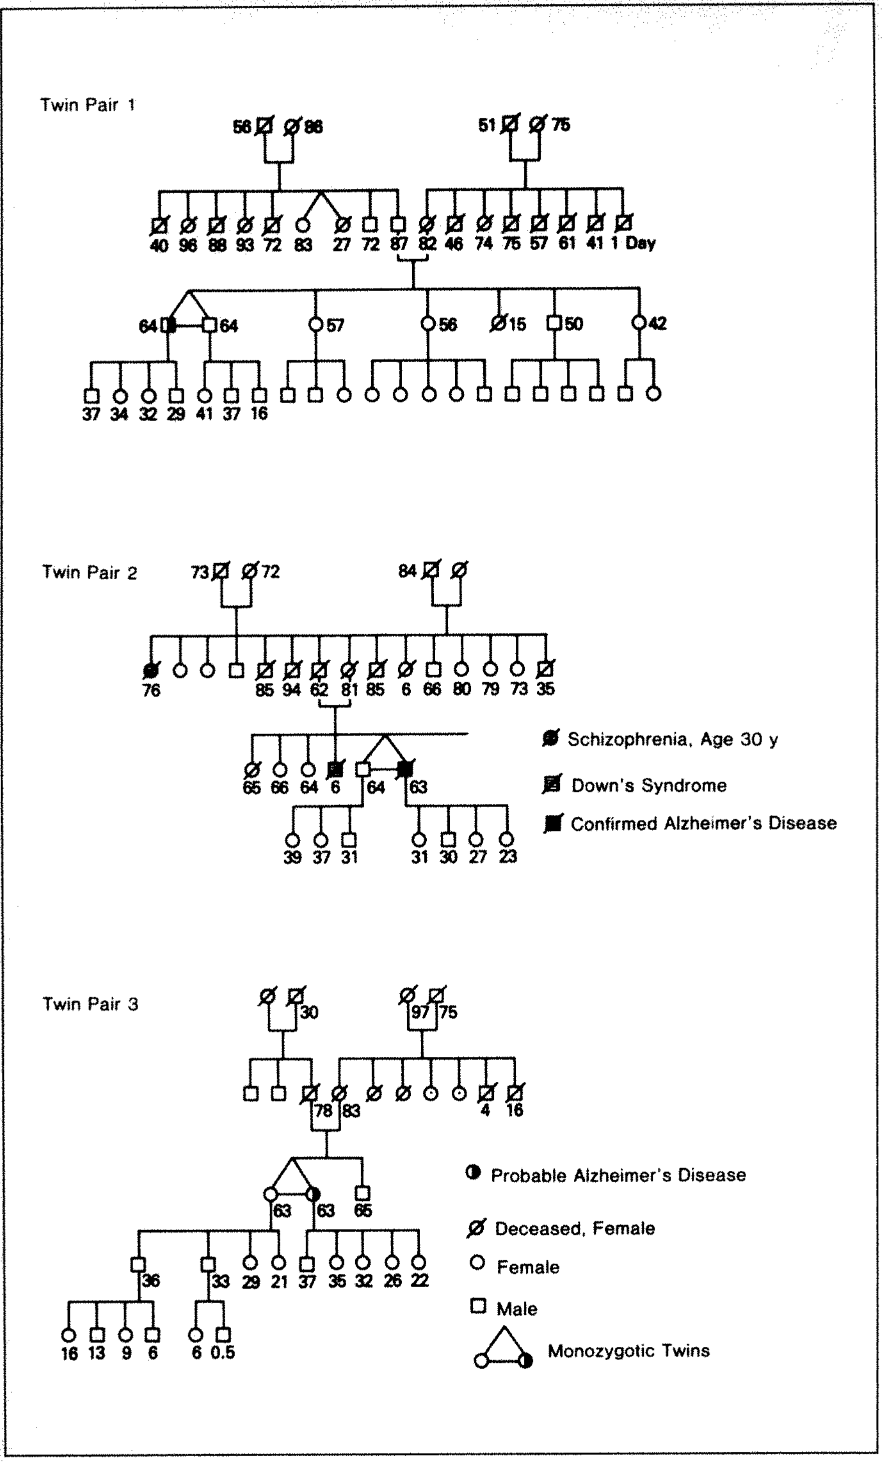

Fig 1.—Dementing illness in twin pair families. There was no evidence of a dementing illness in any family member of each of the affected twins. Half-filled circles and squares represent probable Alzheimer's disease in probands 1A* (twin pair 1) and 3A* (twin pair 3), whereas solid square represents autopsy proved Alzheimer's disease in twin 2A* (twin pair 2). Aunt of twin 2A* was diagnosed as having paranoid schizophrenia at the age of 30 years; a sibling died of Down's syndrome at the age of 6 years.

tia. His Hachinski Ischemic Score equaled 4; a score exceeding 6 suggests multiple infarct disease.[4,5]

Neurological Examination.—In May 1985, twin 1A* appeared alert and cooperative, with marked word-finding difficulty. Upper extremities demonstrated cogwheeling and a fine tremor. Deep tendon reflexes were normal (1+ to 2+ bilaterally), but snout and glabellar reflexes were present. In February 1986, he had no spontaneous speech, with responses limited to a few words. Gait was slow, with bradykinesia and diminished arm swing. In January 1987, he was barely cooperative, with marked cogwheeling of upper extremities and a stooped posture on walking.

The normal twin, 1B, had entirely normal neurological and mental status examination results, with MMSE scores of 26, 29, 25, and 30 in February 1985, February 1986, January 1987, and January 1988, respectively, and a Hachinski Ischemic Score of 4. He had evidence of Raynaud's disease and had a transient ischemic attack in October 1986, but no episode since then.

Twin Pair 2.—Twins 2A* and 2B are white men who were born in June 1925, and were raised in Idaho, where both graduated from high school. After participating in World War II, they returned to Idaho, where each completed 4 years of college. Twin 2A* moved to Montana after he was 30 years old, where he worked as a physical education instructor. Twin 2B worked as an accountant, spending 4 years at a pesticide warehouse, where he may have been exposed to dichlorodiphenyltrichloroethane (DDT) and octachlorotetrahydro - 4,7 - methanoindane (Chlordane). He remains healthy and working.

Medical History and Examination.—Both twins were born by uncomplicated vaginal deliveries, twin 2B being born first. Twin 2A* smoked one pack of cigarettes daily until 1983. The sister of the twins' mother was diagnosed with schizophrenia at the age of 30 years, and that diagnosis was retained until her death (Fig 1, twin pair 2). A brother of the twins had Down's syndrome and died at the age of 6 years. The family history is negative for DAT.

Symptoms in twin 2A* began in 1981; he was diagnosed in 1983 as having DAT. Since he was noted to be hypertensive in 1985, he has been receiving Minipres (prazosin, Pfizer, New York, NY), 2 mg orally daily. In May 1986, he demonstrated mumbling speech with word-finding difficulty and myoclonus. He had cogwheeling of both arms and a diminished arm swing, and he walked with a stooped posture. Reflexes ranged from 1+ to 3+. A grasp reflex was present bilaterally. In July 1987, he displayed prominent dysphasia and was capable only of "yes" and "no" responses. Severe motor apraxia was present. In February 1988, his speech was unintelligible, and he demonstrated glabellar, snout, and grasp reflexes. His MMSE scores were 6, 1, and 0 in September 1985, No-

*Asterisk denotes the twin with a diagnosis of dementia of Alzheimer's type, probable Alzheimer's disease, using National Institute of Neurological and Communicative Disorders and Stroke-Alzheimer's Disease and Related Diseases Association criteria.

†WAIS indicates Wechsler Adult Intelligence Scale; VDQ, Verbal Comprehension Deviation Quotient; MDQ, Memory and Distractibility Deviation Quotient; PDQ, Perceptual Organization Deviation Quotient; NA, not administered; and VF, verbal fluency.

‡Differs from control mean by more than 2 SDs ($P < .05$). Different control samples were used for each twin pair. See text for details.

§Twin 2B could not perform the Stroop Color Word due to color blindness.

vember 1986, and February 1988, respectively, indicative of severe dementia, and his Hachinski Ischemic Score equaled 1.

Three measurements of cerebrospinal fluid concentration of homovanillic acid in twin 2A* made between January 1985 and July 1987 ranged from 31 to 50 nmol/L; closer to the mean found for patients with DAT with extrapyramidal signs including myoclonus (60 nmol/L) than to the mean in patients with DAT without extrapyramidal signs or myoclonus (168 nmol/L).[46] Cerebrospinal fluid concentration of 5-hydroxyindoleacetic acid in twin 2A* measured in September 1985 equaled 61.4 nmol/L, close to the mean of 64 nmol/L for patients with DAT with extrapyramidal symptoms and myoclonus, as compared with the mean for patients with DAT without these signs (116 nmol/L).[46]

Neuropathologic Examination.—Twin 2A* died in September 1988, at the age of 63 years. The pathology report by one of us (M.J.B.) was consistent with an unequivocal diagnosis of Alzheimer's disease, with no evidence of Parkinson's disease. The formalin-fixed brain weighed 1080 g. Corticocerebral atrophy was prominent, particularly in the frontal poles. Large numbers of senile (neuritic) plaques, with occasional well-developed amyloid cores, were found throughout the hippocampal formation bilaterally, where the pyramidal cortex showed enormous numbers of neurofibrillary tangles of the Alzheimer's type, granulovacuolar degeneration, and rodlike Hirano bodies. Large numbers of neurofibrillary tangles also were present in the amygdaloid nuclei, where nerve cell loss was prominent. There was no evidence of congophilic angiopathy. Vast numbers of senile plaques were found throughout the left middle-frontal and left inferotemporal gyri, with neurofibrillary tangles particularly prominent in laminae III and V, and neuronal dropout evident. The densities of neuritic plaques and neurofibrillary tangles in the multiple regions sampled fulfilled the quantitative criteria required for a diagnosis of Alzheimer's disease, proposed by a National Institutes of Health panel.[47]

Nerve cells in the striatum were well preserved, as were neuromelanin-pigmented neurons in both the pars compacta and pars reticulata of each substantia nigra. Extensive search failed to reveal a single intracytoplasmic Lewy inclusion body or a neurofibrillary tangle in either substantia nigra. A modest amount of iron was deposited within the nigrostriatal tract.

The normal twin, 2B, has no reported difficulty in any cognitive function. He has essential hypertension and gout, and is on a regimen of prazosin and zyloprim (Burroughs Wellcome, Research Triangle Park, NC). His blood pressure in August 1987 was 162/90 mm Hg. He was neurologically normal on repeated examinations, with a normal mental status and MMSE scores of 29, 29, and 30 in September 1985, May 1986, and October 1986, respectively. His Hachinski Ischemic Score equaled 1. In September 1985, his cerebrospinal fluid concentration levels of homovanillic acid and 5-hydroxyindoleacetic acid equaled 49 nmol/L and 42 nmol/L, respectively.

Twin Pair 3.—Twins 3A* and 3B, born in June 1926, are white women who were raised in Montana. Both attended college for 1 year, before taking teaching jobs. Both women married at the age of 21 and lived in the same neighborhood until twin 3A* moved to a nursing home 3 years ago. There is no positive family history for DAT (Fig 1, twin pair 3).

Medical History.—Both twins were born at term by uncomplicated vaginal delivery; twin 3B was born first. Intellectual decline in twin 3A* started in 1980. She currently resides in a nursing home.

Neurological Examination.—In April 1986, twin 3A* demonstrated absent spontaneous speech and poor understanding of tasks. In April 1987, her tendon reflexes were 1+ to 2+ bilaterally, with down-going plantar reflexes. In February 1988, there was, additionally, a grasp reflex bilaterally. She was found to have carcinoma of the left breast and underwent a successful radical mastectomy. Her MMSE scores in August 1985, August 1986, and February 1988 were 7, 1, and 0, respectively, and her Hachinski Ischemic Score equaled 1.

The unaffected twin, 3B, is a housewife with normal intellectual and social functioning. The results of her medical and neurological examinations were normal, and she obtained the MMSE scores of 30, 29, and 30 in August 1985, April 1986, and April 1987, respectively. Her Hachinski Ischemic Score equaled 0.

Genetic Analysis

The following blood group and histocompatibility (HLA) antigen determinations were made in each twin pair[48]: (1) HLA antigens: A, B, C, DR; (2) blood group antigens: ABO, Rh (C, Cw, D, E, c, e), MNS (M, N, S, s) P (P1), Kell (K, k, Kp^a, Kp^b), Duffy (Fy^a, Fy^b), Kidd (Jk^a, Jk^b), and Lewis (Le^a, Le^b). Each twin pair was found to be monozygous with respect to each of these antigens. From blood group antigen conformity alone, the likelihood of monozygosity in each twin pair was calculated as $P < .00001$.[49]

No difference in the *Eco*R1 or *Hin*dIII restriction patterns was observed between the affected and the normal twin at any of the three chromosome 21 loci examined. Consequently, no evidence against monozygosity was observed, nor was there evidence of a postzygotic structural defect in chromosome 21 in any affected twin.

Cognitive, Neuroanatomic, and Metabolic Measurements

Neuropsychological test scores on initial examination (Table 1) demonstrated that each affected twin was severely demented, as illustrated by the Mattis Dementia Scale score. Test scores were not recorded if the patient could not comply with instructions. Affected twins 1A* and 3A* showed worsening of dementia over the follow-

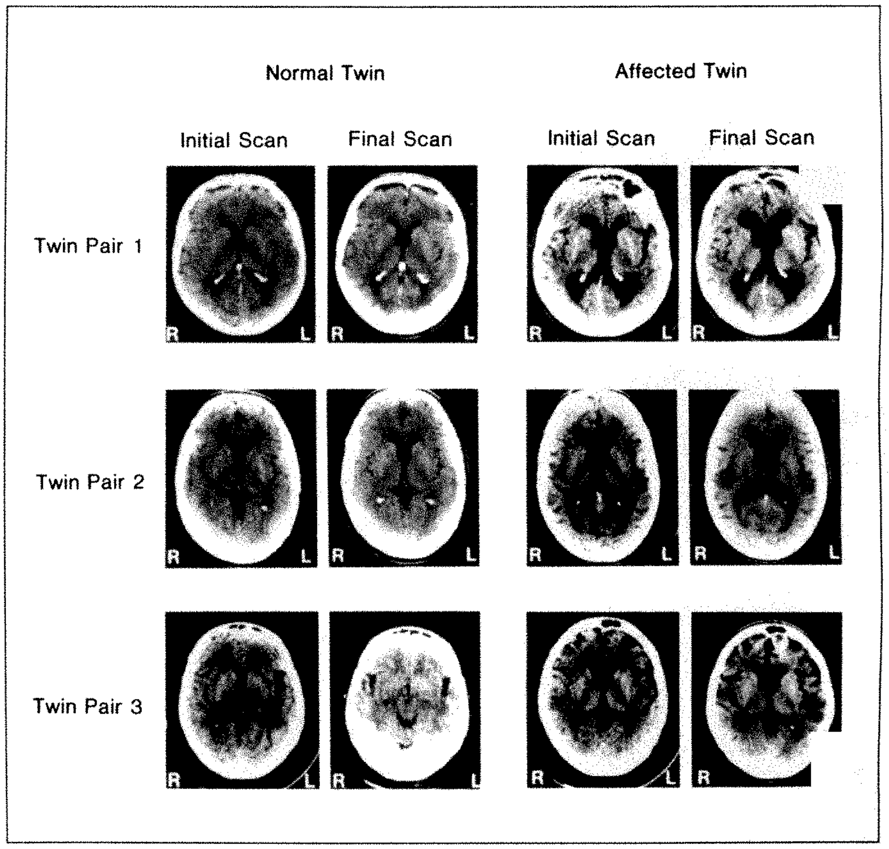

Fig 2.—Initial and final computed tomographic scans of normal and affected twins, at 55 mm above the inferior orbitomeatal line. Computed tomographic scans for twin pair 1 were taken in February 1985 and January 1987 (normal) and in February 1985 and February 1986 (affected); for twin pair 2, in September 1985 and August 1987 (normal) and in September 1985 and June 1987 (affected); and for twin pair 3, in August 1985 and April 1987 (normal) and in May 1985 and April 1987 (affected).

*See footnote to Table 1 for explanation.

†Control subjects include 21 men and 19 women in "Volume" section and 7 men and 4 women in "Rate of Volume Change" section.

‡Differs by 2 SDs from appropriate control mean.

up periods of a year or less, whereas affected twin 2A* did not have lower scores on an 8-month follow-up, but had a reduced Mattis score, of 37, after 29 months (February 1988).

Some initial test scores of normal twin 1B were more than 2 SDs below control means. With one exception (WAIS Perceptual Organization Deviation Quotient), these differences disappeared on subsequent examination. Initial low values may have been due to anxiety, or to the fact that control subjects were more educated than twin 1B (see "Subjects and Methods" section). Some test scores of normal twin 2B also were significantly reduced on initial examination, but on the third (August 1987) and later (March 1988 and March 1990) examinations (not reported in Table 1), cognitive test scores were normal and constant. No test score of normal twin 3B was abnormal, not only at the times noted in Table 1, but in November 1988 as well. No unaffected twin had an abnormal score on the Delayed Story Recall, a test of memory that is characteristically impaired in early DAT.[50-52] Thus, there was no evidence of abnormal or deteriorating cognitive function in normal twins. Function was stable in twin 1B for 2 years, in twin 2B for 5 years, and in twin 3B for more than 3 years.

Figure 2 illustrates initial and final CT scans of normal and affected twins. Whereas ventricular dimensions were read as normal for each unaffected twin, the lateral ventricles in each affected twin were markedly dilated at all times, and severe gyral atrophy was apparent.

Table 2 summarizes volumetric data derived from the CT scans. The net volume of the lateral ventricles of twin 1A* at initial examination equaled 138 cm^3, 6.6 times the mean of 21 cm^3 for age-matched male control subjects, whereas the initial volume of the third ventricle was about twofold higher than the control mean ($P < .05$). The third and right lateral ventricles of twin 2A* and the left lateral ventricle of twin 3A* also were significantly dilated on initial scans. With respect to rates of volume change, the third ventricle of twin 1A*, the left lateral ventricle of twin 2A*, and the right lateral ventricle of twin 3A* dilated more rapidly than in age- and sex-matched control subjects. No abnormal ventricular volume or rate of change of ventricular volume was noted in any unaffected twin (Table 2). Rates of change of lateral ventricular volumes of twin 3B are not given in Table 2 because of the inadequacy of her final CT (Fig 2).

Table 3 summarizes serial $rCMR_{glc}$ values and their ratios to mean gray matter CMR_{glc}, as well as metabolic asymmetries (Equation 1) for each twin. Individual measurements were compared, using a Z-score analysis, with appropriate means for age-, sex-

*ECAT indicates ECAT II tomograph; SCX, Scanditronix tomograph; $rCMR_{glc}$, regional cerebral metabolic rate for glucose; ($rCMR_{glc}/CMR_{glc}$), regional metabolic rate divided by mean gray matter metabolic rate; R-L asymmetry, difference between $rCMR_{glc}$ values on right and left side, divided by their mean (see Equation 1); R, right; and L, left.

†Differs from sex-, age-, and machine-matched control mean[27-30] by 2 SDs ($P < .05$).

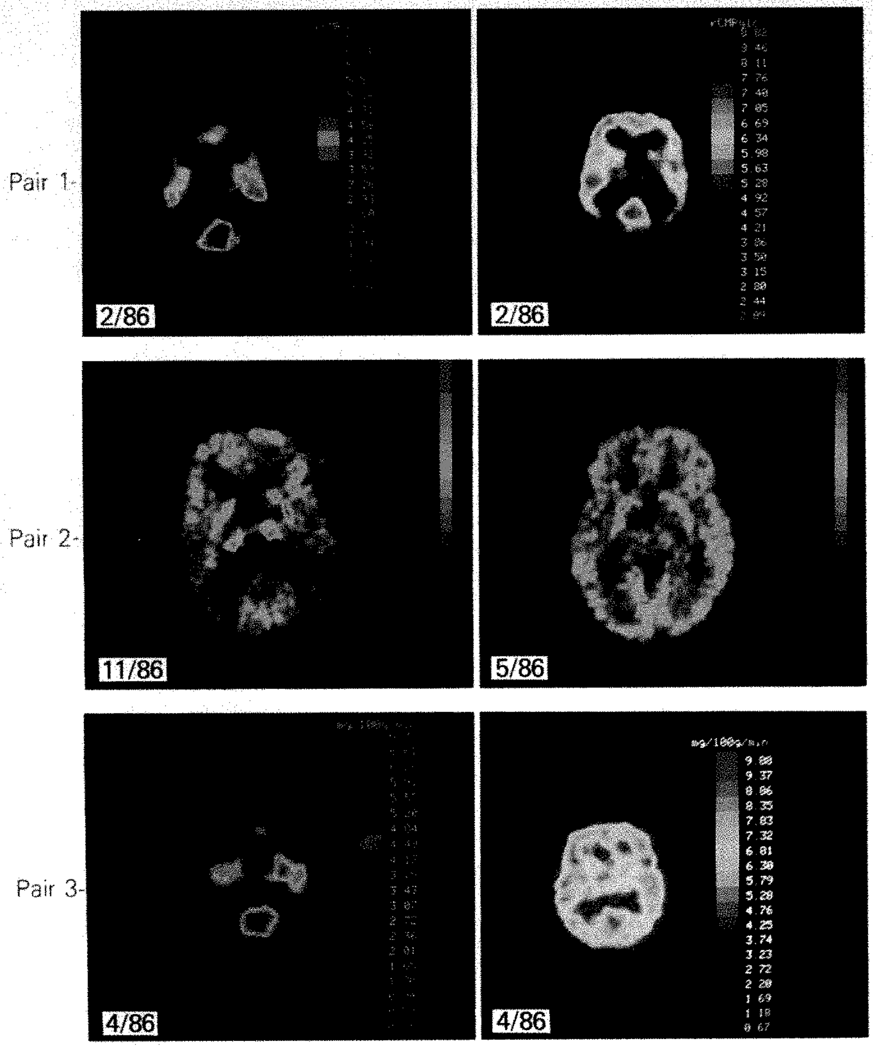

Fig 3.—Positron emission tomographic scans demonstrating cerebral metabolic rates for glucose ($rCMR_{glc}$) in units of $mg \cdot 100\ g^{-1} \cdot min^{-1}$, in affected (left-hand column) and normal (right-hand column) identical twins. Scans are taken at 55 mm above the inferior orbitomeatal line. Scans of twin pairs 1 and 3 are from the ECAT II tomograph, whereas those of twin pair 2 are from the Scanditronix tomograph. Dates of scans are noted in the figure.

and machine-matched control subjects, as reported elsewhere.[27-30] The Scanditronix tomograph provided generally higher recovery rates for $rCMR_{glc}$ than did the ECAT II machine, as described previously.[28]

In each affected twin, most $rCMR_{glc}$ values were more than 2 SDs below the control means ($P < .05$). These reductions also are illustrated in Fig 3. For example, $rCMR_{glc}$ in the right parietal lobe of twin 1A* was 49%, 42%, and 31% of the control mean in his three serial PET scans, and 85%, 74%, and 60% of the control mean in the right calcarine cortex. This decline during 2 years of observation corresponded to declining cognitive test scores (Table 1). The $rCMR_{glc}$ in the right parietal and right calcarine regions of twin 2A* were 39% and 48%, respectively, of the control mean on the first and only scan. For twin 3A*, the $rCMR_{glc}$ values were 46% and 69%, respectively, of the control means. Comparison of data in Table 3 with measurements on patients with DAT by Duara et al[27] shows that each affected twin had $rCMR_{glc}$ values consistent with severe dementia, as measured with the MMSE.

In twin 2A* and twin 3A*, significantly reduced metabolic ratios were apparent in the parietal, temporal and, for twin 3A*, frontal association cortices on the first and only tolerated scans. Twin 1A*, who tolerated three consecutive scans, had consistently reduced metabolic ratios in the frontal and parietal lobes, but not in the temporal lobe.

The metabolic asymmetry index (Equation 1) was unremarkable in twin 2A*, abnormal in the parietal association cortex of twin 3A*, and abnormal in the association cortices in all three scans of twin 1A*. There was no evidence that any PET scan of an unaffected twin showed an abnormal image, except for the initial abnormal metabolic asymmetry index of 2A*, which probably was due to chance. In no unaffected twin was there evidence of worsening of any PET measure.

COMMENT

This study documents discordance of DAT in three twin pairs whose monozygosity was confirmed by extensive HLA and blood group antigen typing. In each twin pair, discordance was demonstrated repeatedly over a period of 2 to 3 years with respect to clinical examination and history, cerebral glucose utilization, and brain ventricular volumes and for 2 to 5 years for neuropsychological test scores. Discordance has been maintained for 11 years in twin pair 1, 8 years in twin pair 2, and 9 years in twin pair 3 (10 years in twin pair 2 and 11 years in twin pair 3 on the basis of cognitive testing alone). No aspect of birth, development, social or medical history, or history of toxic exposure, could distinguish one twin from another, until one developed slowly progressive cognitive impairment diagnosed as DAT.

Postmortem examination of twin 2A* revealed Alzheimer's disease without concurrent Parkinson's disease, even though he had the extrapyramidal signs and myoclonus. This syndrome occurs frequently in moderately to severely demented patients with early onset of DAT, and is accompanied by reduced cerebrospinal levels of homovanillic acid and 5-hydroxyindoleacetic acid.[46] His cerebrospinal fluid profile of these measures was consistent with the group pattern. Absence of neuropathological evidence of Parkinson's disease in twin 2A* indicates that extrapyramidal signs with myoclonus, with cerebrospinal fluid abnormalities, can accompany Alzheimer's disease alone. On the other hand, a recent report[53] indicates that some patients with extrapyramidal signs represent a variant of Alzheimer's disease, with cortical and subcortical Lewy bodies and gross pallor of the substantia nigra.

Twin 2B also had comparatively low levels of cerebrospinal fluid concentrations of homovanillic acid and 5-hydroxyindoleacetic acid. These low values may have been related to his medications.

Although autopsy proofs of Alzheimer's disease in the remaining two affected twins are as yet unavailable, their clinical histories and examinations, together with evidence of worsening cognitive metabolic and anatomic measures and Hachinski Ischemic Scores below 7, make it likely that both had Alzheimer's disease.[23] In our previous studies with this extent of documentation, nine of 10 patients who died with a premorbid diagnosis of DAT (probable Alzheimer's disease, by the National Institute of Neurological and Communicative Disorders and Stroke-Alzheimer's Disease and Related Diseases Association criteria)[23] were shown on postmortem examination to have had Alzheimer's disease.[51]

In so far as cognitive test scores in the unaffected monozygotic twins provide good estimates of premorbid scores in the affected twins,[54,55] the striking differences in IQ and other cognitive measures between the affected and unaffected twins clearly reflect disease in the affected twins. The test profiles in the affected twins correspond to profiles of severely demented patients with DAT, which are characterized by severe impairment in all tests of memory, language, and cognition.[50]

It is likely that initially reduced cognitive test scores for normal twins 1B and 3B. (Table 1) reflected initial anxiety (as the reductions essentially disappeared on later evaluation), and, for twin 1B, his lower educational status as compared with control subjects. In no unaffected twin was a score abnormal on the Delayed Story Recall test, a memory measure usually affected in early DAT.[50-52] Furthermore, longitudinal reevaluation to date has demonstrated no deterioration in any test score, providing evidence for the absence of a progressive, preclinical disease state in each unaffected twin. This conclusion is consistent with the absence of neuroanatomic and cerebral metabolic evidence of abnormality or of deterioration in any unaffected twin.

Enlarged lateral and third ventricles in the affected twins, and abnormal rates of enlargement of their lateral ventricles, characterize patients with DAT.[56,57] In severely demented patients with DAT, however, markedly enlarged lateral ventricles may not show further enlargement (C. DeCarli, MD, oral communication, January 5, 1990). As illustrated by Table 2, no enlargement of the ventricles in any unaffected twin was noted, nor was there any evidence of acceleration of the rate of enlargement of the ventricles.

Regional abnormalities of absolute values of $rCMR_{glc}$, measured with PET, metabolic asymmetry indexes, and metabolic ratios, are found generally in patients with DAT.[27-29,50,58-60] Such abnormalities were evident in each affected twin. For example, PET measurements in twin 1A* demonstrated abnormalities in the association areas, but not in the sensorimotor or calcarine cortices (Table 3). Involvement of the calcarine and sensorimotor regions, as well as the association areas, in the scans of twins 2A* and 3A* and the later scan of 1A*, is found in patients with severe DAT.[27,30]

No unaffected twin demonstrated a consistent cerebral metabolic abnormality on PET. These results support the discordance of each of the three twin pairs, with respect to the metabolic profile of DAT. They also do not indicate any preclinical or related metabolic abnormality in any discordant twin. Indeed, Fulham et al[61] could not identify any PET-related abnormality in the three at-risk subjects who later developed DAT.

To our knowledge, ours is the only reported study of monozygotic twins said to be discordant for DAT, documented with neuropathology (1 case), proved monozygosity, and detailed neuropsychological testing, PET and quantitative CT. Ours also is the only such study, to our knowledge, in which repeated measures between 2 and 5 years have been gathered. In earlier twin studies by Kallmann[5] and Jarvik et al,[8] monozygosity was not proved and diagnoses of "senile psychosis" and "organic brain syndrome in the senium" were used rather than DAT, according to more critical criteria.[23,62] Of discordant DAT twins said to be monozygotic, explicit documentation by HLA and/or blood group antigen typing was presented only by Hunter et al,[6] Renvoize et al,[13] Zubenko and Ferrell,[15] Resnick et al,[16] and Nee et al[14] (three of 10 twins reported). In these latter studies, postmortem confirmation of Alzheimer's disease was provided only by Hunter et al[6] and Renvoize et al.[13]

The rate of discordance for DAT in monozygotic twins has been estimated as 50% to 60%,[14] entirely from single, cross-sectional reports of discordance. However, as appearance of DAT in a previously unaffected twin may occur even after 11 years of apparent discordance,[15] the absence of longitudinal follow-up in prior reports of discordance makes it likely that the discordance rate for DAT is less than 50%.[19]

Our twins have remained discordant with respect to several sensitive measures of brain function, for between 8 to 11 years (10 to 11 years, if cognitive testing alone is considered). As the longest reported difference in age at onset for DAT in concordant monozygotic twins is 11 years,[15] it is likely that each of our twin pairs truly is discordant. Discordance in monozygotic twins has been reported in some individuals for up to 16 and 20 years,[6,13] strongly suggesting that discordance can exist.

Recent evidence indicates that the proximal region of the q arm of human chromosome 21 contains a familial Alzheimer's disease locus that segregates with the disease phenotype in families with early-onset DAT (H. Orr, MD, personal communication)[20,63,64] (but see Roses et al[65]). We found no indication of a structural defect in the close vicinity (10 to 15 kb) of any of the three DNA loci on the proximal long arm of chromosome 21. None of these markers is very close to the familial Alzheimer's disease locus on chromosome 21. There may be additional familial Alzheimer's disease loci on other chromosomes,[20,65] and our analyses would be insensitive to point mutations. Because of these limitations, discordance in each of the three twin pairs cannot yet be attributed to a nongenetic etiology. Until the familial Alzheimer's disease gene is isolated and available as a probe, we cannot rule out a mutation following cleavage of the embryo, rather than the influence of intrauterine or environmental factors.[66-68]

In conclusion, our data indicate prolonged (8 to 11 years) metabolic, structural, and neuropsychological discordance for DAT in three sets of monozygotic twins. The same measures strongly suggest that each of the affected twins had Alzheimer's disease (confirmed by autopsy in 1 case). The unaffected twins continue to show no sign of decline on serial neuropsychological and other testing.

The neuropathology study was supported by grants (to M. J. Ball, MD) from the National Institutes of Health (AG-03047-06A1) and the Atkinson Foundation of Toronto, Ontario. The molecular genetic studies were supported by grants (to P. H. St George-Hyslop, PhD) from the National Institutes of Health (AG-05134 and AG-06865) and the Metropolitan Life Foundation, New York, NY.

This work is part of a collaborative study that makes use of the National Academy of Sciences-National Research Council Twins Registry, Washington, DC. The use of records provided by the Registry, the Department of Defense, the Veterans Administration, and the National Archives and Record Service of the General Services Administration in the preparation of this material is acknowledged, but is not construed as implying official approval by these institutions of the conclusions presented.

The Distribution of Cerebral Muscarinic Acetylcholine Receptors In Vivo in Patients With Dementia

A Controlled Study With ^{123}IQNB and Single Photon Emission Computed Tomography

Daniel R. Weinberger, MD; Raymond Gibson, PhD; Richard Coppola, DSc; Douglas W. Jones, PhD; Susan Molchan, MD; Trey Sunderland, MD; Karen Faith Berman, MD; Richard C. Reba, MD

• A high-affinity muscarinic receptor antagonist, ^{123}IQNB (3-quinuclidinyl-4-iodobenzilate labeled with iodine 123), was used with single photon emission computed tomography to image muscarinic acetylcholine receptors in 14 patients with dementia and in 11 healthy controls. High-resolution single photon emission computed tomographic scanning was performed 21 hours after the intravenous administration of approximately 5 mCi of IQNB. In normal subjects, the images of retained ligand showed a consistent regional pattern that correlated with postmortem studies of the relative distribution of muscarinic receptors in the normal human brain, having high radioactivity counts in the basal ganglia, occipital cortex, and insular cortex, low counts in the thalamus, and virtually no counts in the cerebellum. Eight of 12 patients with a clinical diagnosis of Alzheimer's disease had obvious focal cortical defects in either frontal or posterior temporal cortex. Both patients with a clinical diagnosis of Pick's disease had obvious frontal and anterior temporal defects. A region of interest statistical analysis of relative regional activity revealed a significant reduction bilaterally in the posterior temporal cortex of the patients with Alzheimer's disease compared with controls. This study demonstrates the practicability of acetylcholine receptor imaging with ^{123}IQNB and single photon emission computed tomography. The data suggest that focal abnormalities in muscarinic binding in vivo may characterize some patients with Alzheimer's disease and Pick's disease, but further studies are needed to address questions about partial volume artifacts and receptor quantification.

(*Arch Neurol.* 1991;48:169-176)

A defect in acetylcholinergic neurotransmission is a characteristic feature of Alzheimer's disease (AD). Studies of postmortem tissue[1-10] and of cortical biopsy specimens[6,11-12] from patients with AD have consistently demonstrated reduced markers of presynaptic cholinergic activity. Data about postsynaptic activity, however, have been inconsistent, especially with respect to muscarinic-type cholinergic receptors. While most postmortem studies have not found differences between patients with AD and normal controls in density or affinity of postsynaptic muscarinic receptors,[1,2,5,6,8,13-19] reports of decreased[3,9,20-25] and increased[9,10,26] receptor density have also appeared. The reasons for these discrepancies are uncertain, but they probably involve differences in patient sampling, tissue processing, and assay methodology.[27] Because of such methodological difficulties and the additional possibility that in vivo receptor binding and binding determined in vitro on postmortem tissue may be different,[28,29] the opportunity to study muscarinic receptor binding in vivo in patients with dementia is an important research and clinical agenda.

In 1984, Eckelman et al[30] reported that 3-quinuclidinyl-4-iodobenzilate (IQNB), an iodinated derivative of the high affinity muscarinic receptor antagonist 3-quinuclidinyl benzilate (QNB), could be labeled with iodine 123 and used in conjunction with single photon emission computed tomography (SPECT) to image the distribution of muscarinic receptors in living subjects. They studied one normal individual and one patient with a clinical diagnosis of AD and found in the patient a relative reduction in the retention of the radioactive compound in the left temporoparietal cortex 15 hours after intravenous administration.[31] We report herein our experience

PATIENTS AND METHODS

Patients

Fourteen patients (eight men, six women; mean age, 64.6 years), 12 with a clinical diagnosis of AD and two with a clinical diagnosis of Pick's disease (PD), participated in this study. Each patient had been followed up in the outpatient clinics of the National Institutes of Health, Bethesda, Md, for at least 6 months. Diagnosis was based on *Diagnostic and Statistical Manual of Mental Disorders, Revised Third Edition*, criteria and included a history of gradually progressive intellectual deterioration without focal motor or sensory signs and a laboratory examination that was negative for other significant illnesses. The findings of CT and/or magnetic resonance imaging (MRI) were negative except for signs of generalized atrophy in the patients with AD and frontal-anterior temporal atrophy in the patients thought to have PD. The Hachinski score[32] was less than 4 in each case. The diagnosis of PD was suggested by the presence of frontal lobar atrophy on MRI scan, a history of personality change seemingly out of proportion to the extent of cognitive deterioration, and a profile of neuropsychological deficits suggestive of prominent frontal dysfunction. The Mattis Dementia Scale[33] was administered to each patient prior to the SPECT scan to score general cognitive deficits, which were in the mild to moderate range in most cases. The clinical characteristics of these patients are described in Table 1. Each patient was alert and cooperative at the time of testing, and none was receiving medication with prominent cholinergic effects.

Control Subjects

Eleven normal volunteers (10 men, one woman; mean age, 63.8 years; age range, 42 to 83 years) served as controls. Four control subjects were spouses of patients in the study; the remainder were paid respondents to advertisements in the National Institutes of Health normal volunteer office. Volunteers were carefully screened to exclude individuals with a significant medical and/or psychiatric history and to ensure that they were also medication free. The Mini-Mental State examination[34] was administered at the time of the scan and revealed moderate impairment in two individuals (scores of 19 and 20), both of whom had unremarkable MRI scans and clinical histories, and normal scores in the other subjects (score range, 25 to 29).

Scan Procedure

Iodine 123 was prepared in a cyclotron by the (p,5n) reaction that eliminates contamination with iodine 124. The ^{123}IQNB was synthesized using the Wallach triazene approach, as previously described.[35] Specific activity was determined for each synthesis and averaged 660 Ci/mmol. Each subject received approximately 5 mCi ^{123}IQNB by intravenous injection over a period of 1 to 2 minutes while seated with eyes open. No clinical or subjective effects of the drug were observed. The radiation dosimetry calculated for this dose is 505 mrem to the brain, the organ of maximum exposure after thyroid blockade with Lugol's solution. The subjects remained in the laboratory for approximately 2 hours after administration and then went home.

The subjects came to the scanning room the following day for the SPECT scan. The scan procedure began approximately 21 hours (range, 17 to 24 hours) after injection of the radioligand. The subject was seated in a semireclined position in a comfortable dental chair, which was then raised to bring the head into the scanner gantry. After the head was positioned with external marker lights to set the angle of the slices parallel to, and at set distances from, the canthomeatal line, it was immobilized within the gantry aperture using foam rubber inserts. Most subjects watched a movie on videotape during the procedure to minimize boredom and movement. The scanner is a dedicated head SPECT system (Tomomatic 564, Medimatic Inc, Copenhagen, Denmark) that consists of four detector boxes in a rapidly rotating square array. Each detector box contains 16 sodium iodide scintillation crystals, 25 photomultiplier tubes, and a double-focusing lead collimator.[36] We used a high-resolution collimator that collects four true slices simultaneously (8- to 9-mm resolution [full-width half maximum] in plane, 10 mm thickness, 10-mm gap between slices). After the first scan, the chair was moved down 10 mm, repositioning the head for a second series of slices. This procedure yielded eight contiguous true slices in a total acquisition time of 80 minutes with approximately 750 000 counts per slice. One subject (patient 2) was scanned using a prototype collimator, 6-mm resolution (full-width half maximum) in plane. Images were reconstructed using a standard filtered back projection algorithm that includes attenuation and background corrections.[36] Attenuation correction was performed by the first-order precorrection technique of Kay and Keyes,[37] which utilizes the arithmetic mean of opposing projections. This method employs an attenuation constant and the distance each projection traverses in the attenuating volume to determine the magnitude of the correction factor applied to each projection. We determined the optimum value of the attenuation constant for our scanner configuration empirically, by reconstructing scans of a uniform flood phantom approximating the geometry of the human head and then choosing the value that yielded the most uniform profile for iodine 123. Uniformity and background corrections were applied on a channel-by-channel basis by counting a uniform iodine 123 flood phantom and background count rates immediately prior

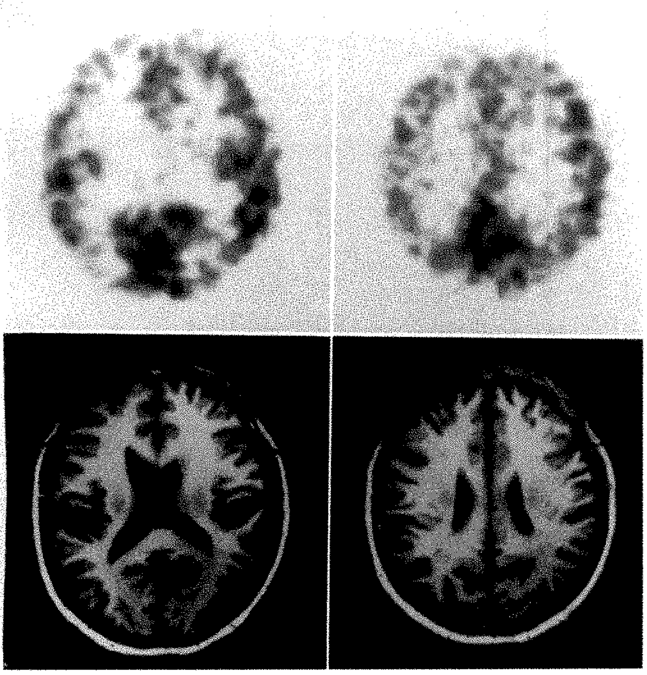

Fig 1.—Iodine 123-labeled 3-quinuclidinyl-4-iodobenzilate single photon emission tomographic images of a normal subject (upper row) and corresponding magnetic resonance imaging scans. Images on the left are cortical slices 20 mm above basal ganglia (BG) level. Images on the right are cortical slices 30 mm above BG level. Left hemisphere is on the left side of the image.

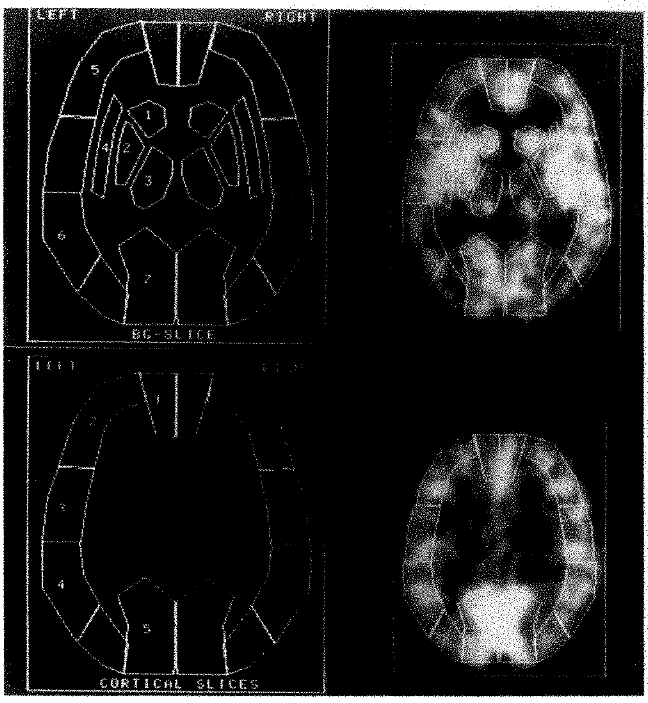

Fig 2.—Region of interest overlay conformed by computer to basal ganglia (BG) slice (upper) and 20-mm cortical slice of iodine 123-labeled 3-quinuclidinyl-4-iodobenzilate single photon emission tomographic images of a normal subject. In the BG slice, 1 corresponds to caudate; 2, putamen; 3, thalamus; 4, insular cortex; 5, frontal cortex; 6, temporal cortex; and 7, occipital cortex. In the cortical slice, 1, medial frontal cortex; 2, lateral frontal; 3, pericentral; 4, temporal; and 5, occipital.

to each scan. Correction was also made for the decay of iodine 123 over the time interval separating the two scan sequences (typically 3% to 4%).

Region of Interest (ROI) Analysis

Based on in vitro autoradiographic data on the distribution of muscarinic receptors in the human brain,[38] and on the results of studies of regional cortical metabolism in patients with AD,[39-43] we selected three SPECT slices for relative distribution analysis: one slice through the basal ganglia (BG), which included caudate and putamen, and two more superior slices through the cortex. The BG slice was determined by referring to the MRI scans (or the CT scans in the case of three patients with AD for whom MRI scans were not available), which included an axial series parallel to the canthomeatal line. In every case, the slice either 30 or 40 mm above the canthomeatal line contained the head of the caudate, putamen, and thalamus. The SPECT slice from the corresponding level for each subject was designated the BG slice for that subject. The SPECT slices 20 and 30 mm above the BG slice were utilized as the superior cortical slices. These slices were usually at the level of the bodies of the lateral ventricles (Fig 1). An anatomically shaped ROI overlay was drawn with a manual cursor using the BG SPECT image from one of the normal subjects as a model (Fig 2). This ROI overlay was then used by computer to generate ROI analyses on each of the slices from each of the subjects. This process involved elastically adapting the ROI overlay to conform to the cortical perimeter of each image. Visual inspection of the images with the ROI overlay in place and of the corresponding MRI or CT images indicated that the elastic adaptation process aligned each of the ROIs with the appropriate anatomical structure as defined by a standard anatomical atlas.[44] From the

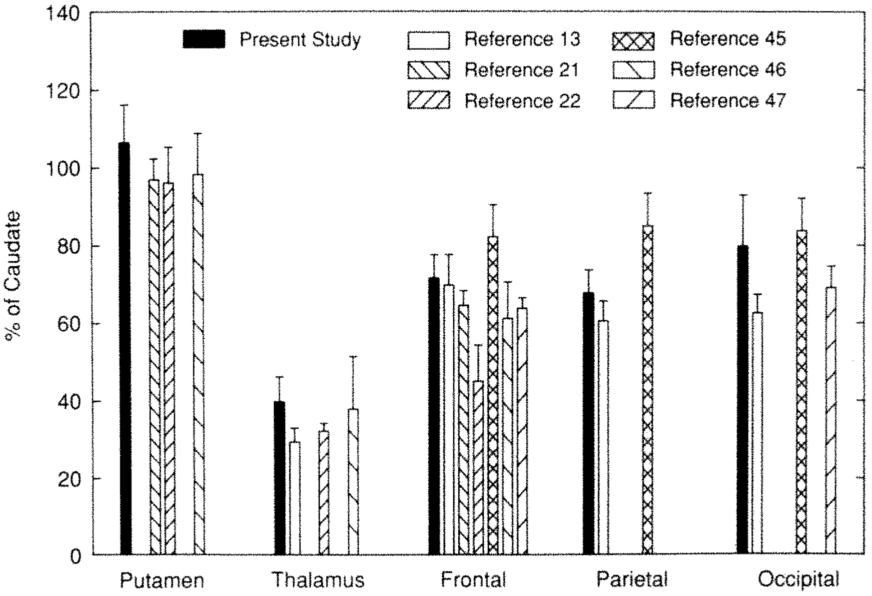

Fig 3.—Comparison of mean (± SD) muscarinic receptor density determined by tritiated QNB radioreceptor assay and iodine 123-labeled 3-quinuclidinyl-4-iodobenzilate single photon emission tomographic data for several brain regions. Tritiated QNB data are taken from in vitro studies in the literature and normalized to caudate (see text).

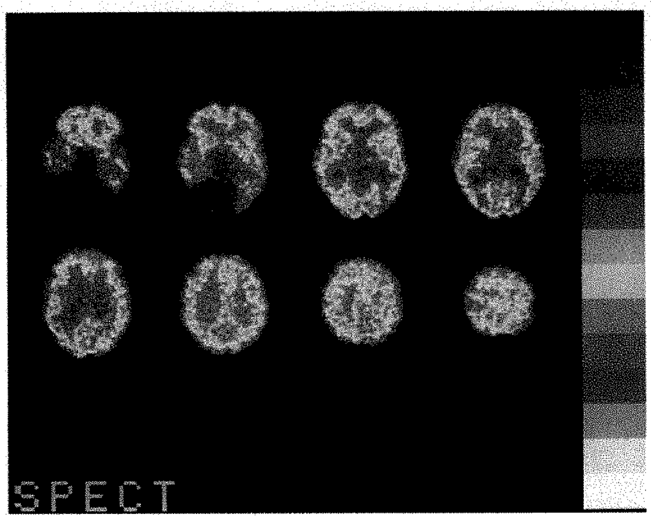
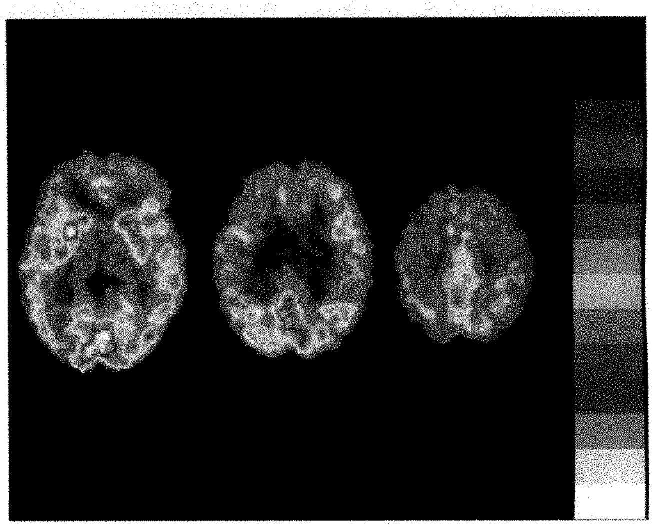
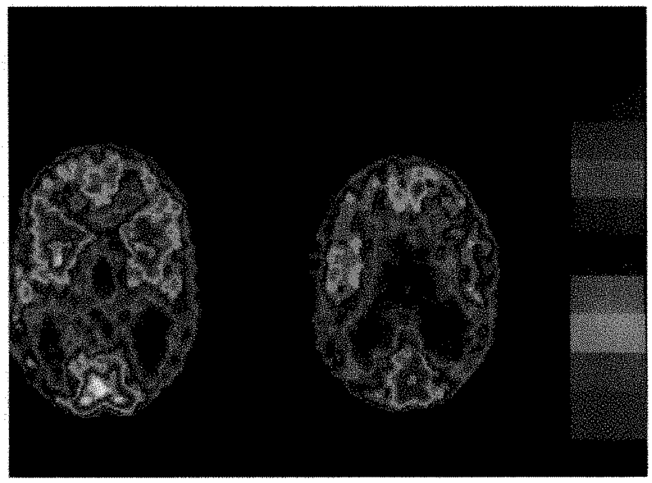


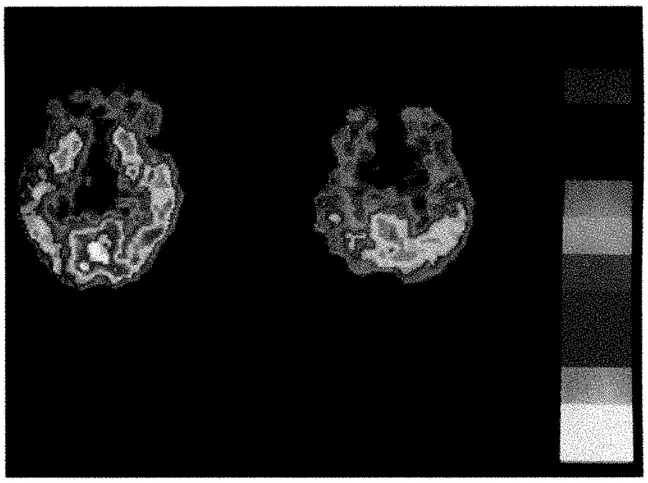
Color Fig 1.—Iodine 123-labeled 3-quinuclidinyl-4-iodobenzilate single photon emission tomography (SPECT) series of eight contiguous horizontal slices in a normal subject beginning with a slice through the posterior fossa (upper left) and ending through the superior cortical gray matter (lower right). Color scale is keyed to relative activity (see text), with white corresponding to 100% and darkest blue to 0%.



Color Fig 3.—Patient 2. Iodine 123-labeled 3-quinuclidinyl-4-iodobenzilate single photon emission tomographic images showing frontal defects. This scan was performed with a prototype collimator, 6-mm resolution in plane (full-width half maximum).



Color Fig 2.—Patient 9. Iodine 123-labeled 3-quinuclidinyl-4-iodobenzilate single photon emission tomographic image through basal ganglia and cortical slice showing posterior temporal defects.



Color Fig 4.—Patient 13. Iodine 123-labeled 3-quinuclidinyl-4-iodobenzilate single photon emission tomographic images showing primarily frontal and anterior temporal defects.

BG slice, the following ROIs were analyzed for each hemisphere: caudate, putamen, thalamus, insular cortex, and inferior frontal, lateral temporal, and occipital cortices. From the cortical slice 20 mm above the BG, the following cortical ROIs were analyzed for each hemisphere: medial frontal, lateral frontal, pericentral, posterior temporal, and occipital. From the cortical slice 30 mm above the BG, the following cortical ROIs were analyzed for each hemisphere: medial frontal, lateral frontal, pericentral, posterior temporal/inferior parietal, and occipital. For technical reasons (eg, misalignment or movement), a full set of SPECT slices was not available for every subject. In addition, the scan of patient 2 was excluded from this analysis because it involved higher resolution.

To control for individual differences in injected dose, specific activity, extraction fraction, and postinjection delay time, we adopted a "percent of range" scale for estimation of the relative distribution of retained isotope concentration based on the mean count rate per unit volume from each ROI. This normalization scheme consisted of the following steps: (1) the mean count rate from the ROI with the lowest mean count rate in the full eight slice series was subtracted from all ROIs on the assumption that it represents "noise" (eg, scatter, background, etc); (2) the mean count rate from the ROI with the highest count rate in this same 80-mm-thick brain volume (typically an ROI corresponding to the cuneus of the occipital lobe) was assigned a value of 100%; and (3) the remaining ROIs were proportionately scaled to percentage values in the range of 0% to 100%.

A two-tailed *t* test was used to examine ROI differences between patients with AD and controls. Because of the multiple comparisons, we selected an α value of .01.

Comparison With In Vitro Studies

To examine the similarity between the relative distribution of ^{123}IQNB in vivo and the relative distribution of muscarinic receptors in the *normal* human brain as determined by tritiated QNB in vitro radioreceptor assay, we identified six postmortem studies[13,21,22,45-47] in the literature that provided receptor density data about several comparable brain areas. For each study, absolute receptor densities from the *normal* control group were converted to relative density by dividing the mean density value for a particular structure by the value for the caudate and then multiplying by 100. A similar scaling procedure was applied to the ROI data from our *control* SPECT images.

RESULTS

Control Subjects

Detailed images with high contrast between gray and white matter were acquired in all subjects (Figs 1 and 2 and color Fig 1). A consistent pattern of cerebral retention of the radioligand was seen in the control subjects. This included highest counts in the BG, insular cortex, and occipital cortex; a fairly even distribution in the rest of the cortex; and relatively low counts in the thalamus. Images through the posterior fossa revealed virtually no counts above background in the cerebellum.

Comparison With In Vitro Studies

Figure 3 illustrates the comparison of the relative distribution of ^{123}IQNB in vivo with muscarinic receptor density in vitro in normal controls. In Fig 5, the relative receptor density in vitro from the various studies is plotted for several brain regions against the relative distribution of IQNB in the scans, illustrating the consistency of the relative regional differences. It is apparent from these figures that there is striking similarity between the data from our in vivo studies and the postmortem data.

Patients With Dementia

In 10 of the 14 patients with dementia, visually obvious cortical irregularities in the distribution of ligand were seen usually in several contiguous slices. The most common pattern in the patients with AD was focal defects in posterior temporal-inferior parietal cortex (five patients, see Table 1 and color Fig 2), which was asymmetric in two patients. Three of the patients with AD had focal defects in frontal cortex (color Fig 3); one of these three also had temporoparietal defects. While these defects tended to correspond to areas of relatively greater atrophy on MRI scan in four cases, they did not in four other cases (see Table 1). The pattern of atrophy on the MRI scans was based on neuroradiologists' interpretations of the scans, which were made blind to the SPECT results. Both of the patients with the clinical diagnosis of PD had dramatic reductions in prefrontal and anterior temporal activity (color Fig 4). In the remaining four patients, no unequivocal focal areas of low activity were seen on visual inspection of the scans.

The results of the ROI analysis are shown in Table 2. As discussed above, several subjects were not included in this analysis. The results indicate that the relative distribution of ^{123}IQNB

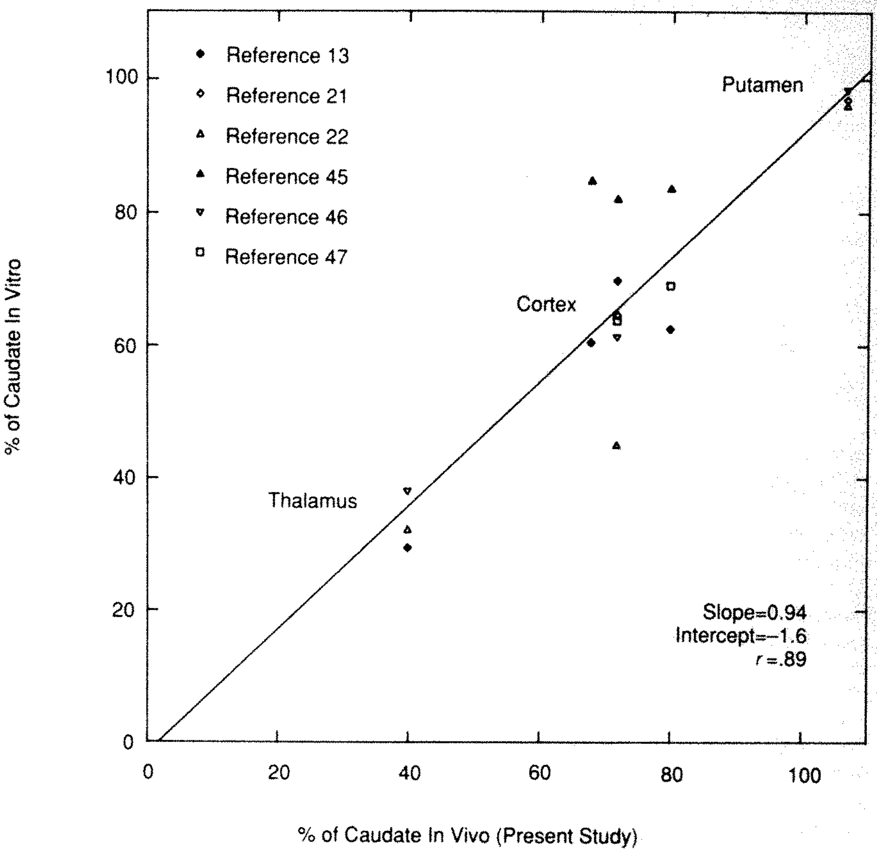


Fig 4.—Plot of mean relative muscarinic receptor density from in vitro studies in the literature as a function of relative iodine 123-labeled 3-quinuclidinyl-4-iodobenzilate single photon emission tomographic data for several brain regions, showing consistent interregional relationships across studies.

*IQNB indicates 3-quinuclidinyl-4-iodobenzilate; ROI, region of interest; BG, basal ganglia; and NS, not significant.

was significantly different for patients with AD and controls in the posterior temporal cortex bilaterally, but not in other regions. Moreover, activity in right posterior temporal cortex was significantly greater than in the left posterior temporal cortex in normals ($t = 2.7$; $P < .03$; matched-pair t test). This asymmetry was not found in the patients with AD.

COMMENT

We have found that ^{123}IQNB is a practical agent for producing high-contrast, high-resolution images of the brain with SPECT. The compound is relatively easy to synthesize and administer; it is well tolerated and involves low-radiation dosimetry and because it is not retained by white matter, the delayed scans have unusually good gray/white matter contrast. In animal studies, IQNB has been shown to be a high-affinity ligand for muscarinic acetylcholine receptors.[48,49] Therefore, one might assume that the images with this agent at extended times postinjection represent the distribution of these receptors. This assumption is supported by the good correlation between the relative distribution of QNB in the normal SPECT scans and the relative distribution of muscarinic receptors in postmortem in vitro binding studies found in the literature. The results of our study also suggest that many patients with primary degenerative dementia may have qualitatively abnormal IQNB SPECT scans. Before considering the possibility that this represents a muscarinic receptor abnormality, several methodological issues will be addressed.

The pharmacological characteristics of IQNB binding in humans have not been systematically investigated. To our knowledge, saturation binding, ligand competition, and stereospecificity studies have not been performed. Therefore, it is presently unconfirmed that this ligand behaves in humans as it does in rats, in which these complimentary studies have been carried out and in which the receptor binding characteristics and peripheral metabolism of IQNB have been well characterized.[48,49] Even if IQNB functions as a muscarinic receptor ligand in humans, it is still possible that its uptake and retention are primarily dependent on blood flow and that the images may reflect blood flow more than receptor distribution. Indeed, the regional patterns of cortical IQNB defects seen in the patients with dementia are similar to those seen with blood flow tracers and SPECT[50-52] and with blood flow and metabolism tracers with positron emission tomography.[39-43]

On the basis of these uncertainties, it could be argued that the IQNB SPECT data provide information primarily about regional cerebral blood flow (rCBF) and that identical information could be acquired with SPECT and rCBF tracers such as iodoamphetamine[50-53] and ^{99m}Tc-HM-PAO.[54-56] We do not believe that this conclusion is correct. In certain brain regions, there was a dramatic dissociation of rCBF and ligand retention at 21 hours. For example, the delayed scans through the posterior fossa showed virtually no radioligand in the cerebellum, which is consistent with the low density of muscarinic receptors in this region[38] but inconsistent with the fact that blood flow to the cerebellum is relatively high.[57] Similarly, retention of radioligand in the thalamus was relatively much lower than in the BG and the cortex, which is consistent with the relative density of muscarinic receptors[38] but not with blood flow in this region.[58] The possibility that low count rate in the thalamus is an artifact of improper attenuation correction is unlikely because this error would have affected the BG as well. Moreover, our preliminary experience in a small group of patients who have undergone both IQNB SPECT and ^{18}F-2-deoxy-2-fluoro-D-glucose positron emission tomography suggests that rCBF, to the extent that it is coupled with regional glucose metabolism, does not adequately account for the IQNB data.[59] Ultimately, to assess the relative contribution of blood flow and specific receptor binding to IQNB images, detailed analyses of uptake and washout characteristics in vivo are required. Judgment on this issue, therefore, must remain reserved until these studies are performed.

It has recently been shown, using molecular genetic techniques, that at least five subtypes of muscarinic receptors exist in the brain.[60] An older, pharmacologically based subclassification scheme has been used to characterize two receptor subtypes, the so-called M1 and M2 receptors.[60,61] It is uncertain which muscarinic receptor subpopulation is labeled with IQNB in vivo. The pattern of distribution in the delayed scans is similar to the distribution of tritiated QNB binding in postmortem studies (Figs 4 and 5). Tritiated QNB binds with high affinity to both M1 and M2 sites.[62] Nevertheless, animal studies suggest that IQNB and tritiated QNB exhibit some differences in receptor kinetics. In vivo binding data in the rat indicate that the dissociation rate constant of IQNB at the M2 receptor is approximately 16 times faster than at the M1 receptor, even though the affinity of IQNB for both receptor subtypes is similar.[48] This difference in dissociation kinetics could account for washout of the tracer predominantly from M2 sites (eg, thalamus) during the 21-hour period from the administration of ligand to the scan. Our preliminary experience with kinetic studies in monkeys (unpublished observations) suggests that washout of radioligand from the thalamus occurs over several hours, which is consistent with the in vivo binding data in the rat.

An unexpected finding in the normal subjects was a lateralized asymmetry in ^{123}IQNB retention in temporal cortex. To our knowledge, this finding has not been reported in postmortem study of normal subjects, perhaps because both hemispheres have not been assayed in the same samples. We did not find this asymmetry in the patients with AD, which is consistent with a postmortem study that assayed regions of both hemispheres in a similar patient population.[63]

The majority of the patients with dementia had qualitatively abnormal scans, characterized by focal areas of relatively reduced retention of radioligand. If this finding primarily reflects receptor binding rather than rCBF, its interpretation is still not straightforward. Despite efforts to develop a model for quantification of muscarinic receptor affinity and density that could be applied to the SPECT data,[64] to our knowledge a satisfactory model does not yet exist. Therefore, it is unknown whether the scan differences between patients and control subjects represent a change in absolute affinity and/or number of muscarinic receptors. For example, it is uncertain whether focal pattern defects represent areas of reduced binding or of normal binding in a brain where other areas are upregulated. Moreover, in the patients who do not have focal defects on the scans, the possibility that they may have widespread but evenly distributed receptor changes cannot be addressed. These caveats notwithstanding, we agree with Di Chiro and Brooks,[65] who emphasized the potential importance of qualitative imaging data, even without absolute quantification.

Several explanations could account for the pattern of focal defects observed in the scans of the patients with dementia. One possibility is that the patients have focal areas of reduced muscarinic receptor density, perhaps because of degenerative changes in the neural tissue on which these receptors reside. This interpretation is intuitively appealing because muscarinic receptors in the cortex appear to reside on large neurons,[8,16,66,67] and this population of cortical neurons is preferentially lost in AD.[68] This interpretation would be consistent with the lack of clinical benefit of muscarinic receptor agonist drugs.[69] Unfortunately, this explanation is inconsistent with the majority of postmortem in vitro binding studies, which have not found areas of reduced muscarinic receptor density.[1,2,5,6,8,13-19] Nevertheless, the data from ^{123}IQNB and SPECT and the postmortem literature in *diseased* individuals are not readily comparable. Patients in the postmortem studies usually were more severely affected, and binding assays in the postmortem studies tend to be performed on very small tissue samples from only a few discrete brain regions. In fact, only two studies reported receptor density in the parietal cortex,[2,13] and it is uncertain whether any study assayed samples from the posterior temporal cortex. Inconsistencies in the in vivo and the postmortem data may also reflect aspects of functional receptor activity that are apparent only in vivo, a possibility that is becoming increasingly recognized in a variety of receptor systems, especially under pathologic circumstances.[28,29] Whether this possibility exists for muscarinic receptors is unknown. It is interesting to note that in contrast to the postmortem studies of AD, the few examples of muscarinic receptor data in patients with PD described reductions in frontal cortex,[2,70] similar to the relative reduction observed in the scans of our two patients with PD.

Another possibility for the pattern of defects in the patients with AD is that the regional findings actually represent areas of normal receptor number and that the other areas, especially those not typically involved in the neuropathologic changes of AD, such as occipital cortex and BG, are regions in which increased muscarinic receptor density results from upregulation in response to cholinergic deafferentation. The possibility that the failure to find decreased muscarinic receptor density in postmortem studies is caused by compensatory upregulation of preserved receptor domains has been raised by several investigators.[2,5,9,13,16,71] Studies of the behavioral effects of muscarinic agonists in patients with AD have suggested hypersensitivity to some of the effects of these drugs.[71] Nevertheless, most of the postmortem studies, even those that assayed relatively nonpathologic sites such as caudate and occipital cortex, did not find evidence of significant receptor upregulation.

A third possibility is that the finding of focal defects in apparent relative binding is the result of a methodological artifact that complicates tomographic scanning of degenerative brain disorders. Because of brain atrophy and loss of tissue volume, volume elements that comprise the image ("voxels") may have reduced radioactivity counts due to inclusion of enlarged cerebrospinal fluid spaces, even though the actual receptor number per volume of tissue is normal (the so-called partial volume artifact).[72] We cannot rule out that this possibility accounts for some of the focal defects. However, we doubt that it explains them all. Areas of focal atrophy corresponding exclusively to areas of relatively reduced radioactive signal were only occasionally apparent on the CT/MRI scans of the patients. Since atrophy tends to be more diffuse than focal in AD, and since all ROI mean counts were normalized to a relatively nonpathologic region (usually occipital cortex), we would have expected a more widespread pattern of relatively reduced cortical "binding" if atrophy-related partial volume artifact accounted for the data. By the same reasoning, we would have expected occipital binding to have been "relatively" greater in the patients than in the controls. In fact, in most cortical regions, the QNB data did not differ from normal, despite widespread cortical volume loss on the MRI/CT scans. In our experience with another tomographic technique (positron emission tomography) in some of the same patients, the pattern of distribution of activity differed considerably in some cases,[59] which would not have been expected if partial volume phenomena alone accounted for the patterns.

In conclusion, high-resolution images of the retention of a muscarinic acetylcholine receptor ligand in the human brain can be achieved in essentially routine clinical practice with SPECT imaging and ^{123}IQNB. It is likely that the images reflect the distribution of the relative density of a subpopulation of muscarinic receptors. The majority of the patients with primary degenerative dementia had qualitatively abnormal IQNB SPECT scans, perhaps because of focal areas of reduced receptor density. This possibility and the potential clinical utility of this technique will remain uncertain until further studies are conducted and possibly until an in vivo model for quantification of receptor density and affinity with this ligand is developed.

This study was supported, in part, by US Public Health Service grant NS22215.

The authors thank Julie Gorey, CNMT, for invaluable technical assistance, Dr Parvathi P. Hosain for help with 3-quinuclidinyl-4-iodobenzilate (IQNB) synthesis and Dr Barry Zeeberg for technical help and for his critical review of the manuscript.

ANTICONVULSANT BULLETIN

New evidence: No difference between the cognitive effects of phenytoin and carbamazepine

Turn page for the results of an important new study.

ANTICONVULSANT BULLETIN

Results from:
Comparative cognitive effects of anticonvulsants

K.J. Meador, D.W. Loring, K. Huh, B.B. Gallagher, D.W. King
Neurology. 1990;40:391-394.

Patients receiving phenytoin and carbamazepine had virtually identical cognitive performances[1]

- Fifteen seizure patients treated with phenytoin, carbamazepine, and phenobarbital for 3 months each were given a cognitive evaluation at the end of each treatment period[1]
- Cognitive tests were designed to assess deficits associated with anticonvulsants—impairments in memory, information processing, attention/concentration, and motor speed[1]
- Mean cognitive scores and individual responses failed to suggest a trend toward differential effects[1]

Mean scores* for cognitive measures

Cognitive Measures	Carbamazepine	Phenytoin	Phenobarbital
Grapho-Motor Coding	48	48	43
Simple Attention†	5.5	5.5	5.7
Simple Attention‡	4.0	4.5	4.5
Selective Reminding Test	53	59	49
Repetitive Motor Speed	46	45	44
Coordination/Motor Speed	72	73	74
Decisional/Motor Speed	698	705	737

—adapted from Meador et al, p 392[1]

*On Decisional/Motor Speed, it was desirable to achieve as *low* a score as possible. On all other tests, it was desirable to achieve as *high* a score as possible. However, there was no significant difference between scores of the three anticonvulsants on any test with the exception of Grapho-Motor Coding—the score for phenobarbital was significantly worse than for the other two anticonvulsants.

†Digit Span Forward. ‡Digit Span Backward.

Rigorous study design helped prevent patient selection bias—a flaw of most earlier studies

- Randomized, double-blind, triple-crossover study design helped prevent patient selection bias[1]
- Dosages were adjusted to be within the standard therapeutic range (phenytoin, 10 to 20 μg/mL; carbamazepine, 6 to 12 μg/mL; phenobarbital, 15 to 40 μg/mL)[1]

Dilantin® Kapseals®

(extended phenytoin sodium capsules, USP)

Dilantin® KAPSEALS® (Extended Phenytoin Sodium Capsules, USP)

Before prescribing, please see full prescribing information. A Brief Summary follows.

INDICATIONS AND USAGE: Dilantin is indicated for the control of generalized tonic-clonic (grand mal) and complex partial (psychomotor, temporal lobe) seizures and prevention and treatment of seizures occurring during or following neurosurgery.

Phenytoin serum level determinations may be necessary for optimal dosage adjustments (see Dosage and Administration and Clinical Pharmacology in the full prescribing information).

CONTRAINDICATIONS: Phenytoin is contraindicated in those patients who are hypersensitive to phenytoin or other hydantoins.

WARNINGS: Abrupt withdrawal of phenytoin in epileptic patients may precipitate status epilepticus. When, in the judgment of the clinician, the need for dosage reduction, discontinuation, or substitution of alternative antiepileptic medication arises, this should be done gradually. However, in the event of an allergic or hypersensitivity reaction, rapid substitution of alternative therapy may be necessary. In this case, alternative therapy should be an antiepileptic drug not belonging to the hydantoin chemical class.

There have been a number of reports suggesting a relationship between phenytoin and the development of lymphadenopathy (local or generalized) including benign lymph node hyperplasia, pseudolymphoma, lymphoma, and Hodgkin's Disease. Although a cause and effect relationship has not been established, the occurrence of lymphadenopathy indicates the need to differentiate such a condition from other types of lymph node pathology. Lymph node involvement may occur with or without symptoms and signs resembling serum sickness, eg, fever, rash and liver involvement.

In all cases of lymphadenopathy, follow-up observation for an extended period is indicated and every effort should be made to achieve seizure control using alternative antiepileptic drugs.

Acute alcoholic intake may increase phenytoin serum levels while chronic alcoholic use may decrease serum levels.

In view of isolated reports associating phenytoin with exacerbation of porphyria, caution should be exercised in using this medication in patients suffering from this disease.

Usage in Pregnancy: A number of reports suggests an association between the use of antiepileptic drugs by women with epilepsy and a higher incidence of birth defects in children born to these women. Data are more extensive with respect to phenytoin and phenobarbital, but these are also the most commonly prescribed antiepileptic drugs; less systematic or anecdotal reports suggest a possible similar association with the use of all known antiepileptic drugs.

The reports suggesting a higher incidence of birth defects in children of drug-treated epileptic women cannot be regarded as adequate to prove a definite cause and effect relationship. There are intrinsic methodological problems in obtaining adequate data on drug teratogenicity in humans; genetic factors or the epileptic condition itself may be more important than drug therapy in leading to birth defects. The great majority of mothers on antiepileptic medication deliver normal infants. It is important to note that antiepileptic drugs should not be discontinued in patients in whom the drug is administered to prevent major seizures, because of the strong possibility of precipitating status epilepticus with attendant hypoxia and threat to life. In individual cases where the severity and frequency of the seizure disorder are such that the removal of medication does not pose a serious threat to the patient, discontinuation of the drug may be considered prior to and during pregnancy, although it cannot be said with any confidence that even minor seizures do not pose some hazard to the developing embryo or fetus. The prescribing physician will wish to weigh these considerations in treating or counseling epileptic women of childbearing potential.

In addition to the reports of increased incidence of congenital malformation, such as cleft lip/palate and heart malformations, in children of women receiving phenytoin and other antiepileptic drugs, there have more recently been reports of a fetal hydantoin syndrome. This consists of prenatal growth deficiency, microcephaly and mental deficiency in children born to mothers who have received phenytoin, barbiturates, alcohol, or trimethadione. However, these features are all interrelated and are frequently associated with intrauterine growth retardation from other causes.

There have been isolated reports of malignancies, including neuroblastoma, in children whose mothers received phenytoin during pregnancy.

An increase in seizure frequency during pregnancy occurs in a high proportion of patients, because of altered phenytoin absorption or metabolism. Periodic measurement of serum phenytoin levels is particularly valuable in the management of a pregnant epileptic patient as a guide to an appropriate adjustment of dosage. However, postpartum restoration of the original dosage will probably be indicated.

Neonatal coagulation defects have been reported within the first 24 hours in babies born to epileptic mothers receiving phenobarbital and/or phenytoin. Vitamin K has been shown to prevent or correct this defect and has been recommended to be given to the mother before delivery and to the neonate after birth.

PRECAUTIONS: General: The liver is the chief site of biotransformation of phenytoin; patients with impaired liver function, elderly patients, or those who are gravely ill may show early signs of toxicity.

A small percentage of individuals who have been treated with phenytoin has been shown to metabolize the drug slowly. Slow metabolism may be due to limited enzyme availability and lack of induction; it appears to be genetically determined.

Phenytoin should be discontinued if a skin rash appears (see "Warnings" section regarding drug discontinuation). If the rash is exfoliative, purpuric, or bullous or if lupus erythematosus, Stevens-Johnson syndrome, or toxic epidermal necrolysis is suspected, use of this drug should not be resumed and alternative therapy should be considered. (See Adverse Reactions.) If the rash is of a milder type (measles-like or scarlatiniform), therapy may be resumed after the rash has completely disappeared. If the rash recurs upon reinstitution of therapy, further phenytoin medication is contraindicated.

Phenytoin and other hydantoins are contraindicated in patients who have experienced phenytoin hypersensitivity. Additionally, caution should be exercised if using structurally similar (eg, barbiturates, succinimides, oxazolidinediones and other related compounds) in these same patients.

Hyperglycemia, resulting from the drug's inhibitory effects on insulin release, has been reported. Phenytoin may also raise the serum glucose level in diabetic patients.

Osteomalacia has been associated with phenytoin therapy and is considered to be due to phenytoin's interference with Vitamin D metabolism.

Phenytoin is not indicated for seizures due to hypoglycemic or other metabolic causes. Appropriate diagnostic procedures should be performed as indicated.

Phenytoin is not effective for absence (petit mal) seizures. If tonic-clonic (grand mal) and absence (petit mal) seizures are present, combined drug therapy is needed.

Serum levels of phenytoin sustained above the optimal range may produce confusional states referred to as "delirium," "psychosis," or "encephalopathy," or rarely irreversible cerebellar dysfunction. Accordingly, at the first sign of acute toxicity, plasma levels are recommended. Dose reduction of phenytoin therapy is indicated if plasma levels are excessive; if symptoms persist, termination is recommended. (See Warnings.)

Information for Patients: Patients taking phenytoin should be advised of the importance of adhering strictly to the prescribed dosage regimen, and of informing the physician of any clinical condition in which it is not possible to take the drug orally as prescribed, eg, surgery, etc.

Patients should also be cautioned on the use of other drugs or alcoholic beverages without first seeking the physician's advice.

Patients should be instructed to call their physician if skin rash develops.

The importance of good dental hygiene should be stressed in order to minimize the development of gingival hyperplasia and its complications.

Do not use capsules which are discolored.

Laboratory Tests: Phenytoin serum level determinations may be necessary to achieve optimal dosage adjustments.

Drug Interactions: There are many drugs which may increase or decrease phenytoin levels or which phenytoin may affect. Serum level determinations for phenytoin are especially helpful when possible drug interactions are suspected. The most commonly occurring drug interactions are listed below: 1. Drugs which may increase phenytoin serum levels include: acute alcohol intake, amiodarone, chloramphenicol, chlordiazepoxide, diazepam, dicumarol, disulfiram, estrogens, H_2-antagonists, halothane, isoniazid, methylphenidate, phenothiazines, phenylbutazone, salicylates, succinimides, sulfonamides, tolbutamide, trazodone.

2. Drugs which may decrease phenytoin levels include: carbamazepine, chronic alcohol abuse, reserpine, and sucralfate. Moban® brand of molindone hydrochloride contains calcium ions which interfere with the absorption of phenytoin. Ingestion times of phenytoin and antacid preparations containing calcium should be staggered in patients with low serum phenytoin levels to prevent absorption problems.

3. Drugs which may either increase or decrease phenytoin serum levels include: phenobarbital, sodium valproate, and valproic acid. Similarly, the effect of phenytoin on phenobarbital, valproic acid and sodium valproate serum levels is unpredictable.

4. Although not a true drug interaction, tricyclic antidepressants may precipitate seizures in susceptible patients and phenytoin dosage may need to be adjusted.

5. Drugs whose efficacy is impaired by phenytoin include: corticosteroids, coumarin anticoagulants, digitoxin, doxycycline, estrogens, furosemide, oral contraceptives, quinidine, rifampin, theophylline, vitamin D.

Drug/Laboratory Test Interactions: Phenytoin may cause decreased serum levels of protein-bound iodine (PBI). It may also produce lower than normal values for dexamethasone or metyrapone tests. Phenytoin may cause increased serum levels of glucose, alkaline phosphatase, and gamma glutamyl transpeptidase (GGT).

Carcinogenesis: See "Warnings" section for information on carcinogenesis.

Pregnancy: See Warnings.

Nursing Mothers: Infant breast-feeding is not recommended for women taking this drug because phenytoin appears to be secreted in low concentrations in human milk.

ADVERSE REACTIONS: Central Nervous System: The most common manifestations encountered with phenytoin therapy are referable to this system and are usually dose-related. These include nystagmus, ataxia, slurred speech, decreased coordination and mental confusion. Dizziness, insomnia, transient nervousness, motor twitchings, and headaches have also been observed. There have also been rare reports of phenytoin induced dyskinesias, including chorea, dystonia, tremor and asterixis, similar to those induced by phenothiazine and other neuroleptic drugs.

A predominantly sensory peripheral polyneuropathy has been observed in patients receiving long-term phenytoin therapy.

Gastrointestinal System: Nausea, vomiting, constipation, toxic hepatitis and liver damage.

Integumentary System: Dermatological manifestations sometimes accompanied by fever have included scarlatiniform or morbilliform rashes. A morbilliform rash (measles-like) is the most common; other types of dermatitis are seen more rarely. Other more serious forms which may be fatal have included bullous, exfoliative or purpuric dermatitis, lupus erythematosus, Stevens-Johnson syndrome, and toxic epidermal necrolysis (see Precautions).

Hemopoietic System: Hemopoietic complications, some fatal, have occasionally been reported in association with administration of phenytoin. These have included thrombocytopenia, leukopenia, granulocytopenia, agranulocytosis, and pancytopenia with or without bone marrow suppression. While macrocytosis and megaloblastic anemia have occurred, these conditions usually respond to folic acid therapy. Lymphadenopathy including benign lymph node hyperplasia, pseudolymphoma, lymphoma, and Hodgkin's Disease have been reported (see Warnings).

Connective Tissue System: Coarsening of the facial features, enlargement of the lips, gingival hyperplasia, hypertrichosis and Peyronie's Disease.

Cardiovascular: Periarteritis nodosa.

Immunologic: Hypersensitivity syndrome (which may include, but is not limited to, symptoms such as arthralgias, eosinophilia, fever, liver dysfunction, lymphadenopathy or rash), systemic lupus erythematosus, immunoglobulin abnormalities.

OVERDOSAGE: The lethal dose in children is not known. The lethal dose in adults is estimated to be 2 to 5 grams. The initial symptoms are nystagmus, ataxia, and dysarthria. Other signs are tremor, hyperreflexia, lethargy, slurred speech, nausea, vomiting. The patient may become comatose and hypotensive. Death is due to respiratory and circulatory depression.

There are marked variations among individuals with respect to phenytoin plasma levels where toxicity may occur. Nystagmus, on lateral gaze, usually appears at 20 mcg/mL, ataxia at 30 mcg/mL, dysarthria and lethargy appear when the plasma concentration is over 40 mcg/mL, but as high a concentration as 50 mcg/mL has been reported without evidence of toxicity. As much as 25 times the therapeutic dose has been taken to result in a serum concentration over 100 mcg/mL with complete recovery.

Treatment: Treatment is nonspecific since there is no known antidote.

The adequacy of the respiratory and circulatory systems should be carefully observed and appropriate supportive measures employed. Hemodialysis can be considered since phenytoin is not completely bound to plasma proteins. Total exchange transfusion has been used in the treatment of severe intoxication in children.

In acute overdosage the possibility of other CNS depressants, including alcohol, should be borne in mind.

Widespread Functional Effects of Discrete Thalamic Infarction

Brigitte Szelies, MD; Kare Herholz, MD; Gunther Pawlik, MD; Hans Karbe, MD;
Ira Hebold, MD; Wolf-Dieter Heiss, MD

• In order to investigate functional effects of various thalamic structures on metabolism in remote, morphologically intact cerebral regions, we used positron emission tomography of (^{18}F)-2-fluoro-2-deoxy-D-glucose to study regional cerebral metabolic rates of glucose (rCMRGlu) in 11 patients with chronic unilateral or bilateral infarcts strictly confined to the thalamus. Patients were grouped according to computed tomographic scans showing anterior (three), medial (four), or posterior (four) lesions. Compared with a matched group of 11 healthy subjects (hemispheric CMRGlu 35.2 ± 3.49 μmol/100 g per minute), glucose metabolism was significantly lower in the hemisphere ipsilateral to the infarction (31.2 ± 2.97 μmol/100 g per minute). Patients with bilateral infarcts had lower hemispheric CMRGlu (29.9 ± 2.74 μmol/100 g per minute) than those with unilateral lesions (32.2 ± 2.97 μmol/100 g per minute). Depending on infarct location within the thalamus, there was differential depression of rCMRGlu, with the largest effects on frontal and occipital areas in medial infarctions. Except for ipsilateral thalamic deactivation, metabolic patterns with anterior thalamic infarcts were close to normal, while posterior infarcts mostly depressed rCMRGlu in the visual and in the inferior limbic cortex. Cerebellar metabolic rates were within normal limits in most cases. These patterns of regional cerebral deactivation may be related to categories of thalamic projections—intrathalamic, to limbic system and basal ganglia, diffuse to most cortical areas, and specific to defined neocortical areas. Even small brain lesions may have widespread functional sequelae, potentially demonstrable by positron emission tomography.

(*Arch Neurol.* 1991;48:178-182)

Functional hypometabolism in morphologically intact projection areas distant from the site of a typical cerebral infarct is a common finding in positron emission tomography (PET) of ischemic stroke.[1-6] The main cause of this transneural depression called diaschisis by von Monakow[7] was suggested to be the interruption of afferent projection systems,[8] but with chronic infarcts anterograde, wallerian degeneration may also be of functional importance.[9] Additionally, retrograde and transsynaptic degeneration secondary to the disruption of afferent pathways may play a role. The extent of remote metabolic deactivation is dependent mainly on the location of an infarct, but also the size and the severity of the ischemic damage were shown to modulate the degree of hypometabolism in areas of the central nervous system connected to the lesioned structure.[6] The thalamus being the most important relay station in the brain, modulates and coordinates almost all other cerebral functions; its projections reach nearly all areas of the telencephalon, sparing only a few.[10] From the experience with lesions in other brain structures it might be expected that rather limited destruction of the diencephalon entails metabolic depression of various distant, but functionally related, areas. However, most studies so far have investigated the effect of large subcortical lesions involving the thalamus and large fibrous projection systems, eg, in the internal capsule, and have found widespread depressions of metabolism or blood flow in the ipsilateral cortex.[11-18]

Less marked effects were also observed in the contralateral hemisphere. Regional differences of cortical depression, depending on the site of the thalamic lesion, were reported,[12] but, in contrast to animal experiments, where isolated lesions of the ventromedial thalamic nuclei caused marked decreases in metabolism of the respective cortical projection areas,[19] significant correlations could not be established in small patient series.[13] In all these previous studies, however, no clear distinction was made between discrete thalamic infarcts and those involving other subcortical structures, eg, the internal capsule, and therefore remote effects caused by thalamic nuclear destruction were not distinguished from those caused by interruption of fiber systems. It was the aim of this study to investigate the effect of chronic infarcts strictly confined to the thalamus on brain glucose metabolism in relation to thalamocortical projections.

SUBJECTS, MATERIALS, AND METHODS

Eleven patients, six females, five males, aged 39 to 67 years (mean age, 53.8 years), with unilateral or bilateral thalamic infarction, were studied. The diagnosis of ischemic stroke, which had occurred 7 months to 9 years before the PET study, was based on a typical history confirmed by a complete neurologic workup, including a computed tomographic (CT) scan obtained 1 to 5 days prior to PET. Magnetic resonance imaging scans that were available only in some cases were not consulted, in order to avoid undue chronological sample bias. Rather the CT (Somatom DR, Siemens) was used to localize the infarct and to rule out cases with involvement of structures other than the thalamus. Five infarcts were located in the left thalamus, one in the right thalamus, and five patients had bilateral thalamic infarction. Three infarcts involved mainly the anterior, four mainly the medial, and four the (ventrolateral) posterior thalamic regions. Three of the medial and one each of the posterior and anterior infarcts were bilateral. Clinical assessment of these patients with chronic thalamic infarction (Table 1) revealed dementia with prominent amnesia in seven cases; three patients presented with aphasic syndromes, with anomia in two and articulatory initiation problems in one case. Three patients suffered from (incomplete) Déjerine-Roussy syndrome with thalamic pain. In none of our cases, loss of motor or sensory function indicated a lesion of internal capsule or midbrain structures, thus providing further evidence to the fact that only patients with infarcts restricted to the thalamus were studied.

After written informed consent had been obtained from the patient whenever possible, and/or from his next of kin, brain glucose metabolism (CMRGlu) was studied with 2(^{18}F)-fluoro-2-deoxy-D-glucose (FDG) and PET,[20] using a four-ring positron camera (Scanditronix PC-384) simultaneously scanning seven slices (11 mm in thickness)

*Values for regional cerebral metabolic rate of glucose are given in micromoles per 100 g per minute. Values are means ± SDs.

†Noninfarcted tissue only.

at an in-slice spatial resolution of 7.8 mm full width at half maximum height (FWHM).[21] After patient positioning by means of laser beams and skin marks, 185 MBq (5 mCi) FDG synthesized according to the method of Ehrenkaufer et al[22] was injected intravenously, with the patient resting in a darkened room with low ambient noise, eyes closed, and ears unoccluded. The first set of seven tomograms was recorded from 30 to 40 minutes after injection, the patients were then axially shifted by 7 mm to permit the scanning of an additional set of seven intercalated slices. Investigative and scanning procedures, as well as image processing, were performed as described in detail elsewhere.[23] The CMRGlu in the 14 parallel slices scanned between 30 and 50 minutes after FDG injection was calculated using a lumped constant of 0.42 and rate constants adjusted for the measured tissue activities according to a K_1-k_3 optimization procedure[24] requiring less stringent assumptions about the tracer behavior in abnormal tissue. Standardized regional quantitation was achieved by means of an interactive mapping program[25] and a categorical region-matching and block-shifting procedure[26] providing optimal comparability among subjects. The effect of anterior, medial, or posterior thalamic infarction on CMRGlu was studied in 14 cluster brain regions usually comprising several slices: brain stem, cerebellum, white matter, unaffected thalamus, caudate and lentiform nucleus, and frontal, lateral temporal, mesiotemporal, insular, parietal, sensorimotor, visual, and cingulate cortex. These data were compared with the results obtained in 11 healthy subjects matched for age and sex. No attempt was made to establish a control group with mild systemic or cardiovascular health problems, because such risk factors apparently have no significant effect on brain metabolism,[27] while patients with extrathalamic stroke do not lend themselves for comparison, considering their prominent deactivation pattern.[6]

Hemispheric CMRGlu was calculated as the average of all regional CMRGlu values weighted by region size. In normal subjects and patients with bilateral infarcts, averages of both hemispheres and of corresponding regions within both hemispheres were calculated and used for further analysis, whereas in patients with unilateral infarcts ipsilateral and contralateral hemispheres were treated separately. Data were analyzed by analysis of variance (ANOVA), with the regions representing the levels of a within-subject factor, using the Huynh and Feldt[28] correction of degrees of freedom. Values are given as means ± SDs.

RESULTS

Effects of Thalamic Infarction on Hemispheric Metabolic Rate

The mean (ipsilateral) hemispheric and regional CMRGlu of the 11 patients with thalamic infarction, and of the volunteer subjects, are summarized in Table 2. In a comparison of control subjects vs patients (hemispheres ipsilateral to infarct only), hemispheric CMRGlu was significantly lower in patients ($P = .009$). Comparing patients with bilateral infarcts vs ipsilateral and contralateral hemispheres of patients with unilateral infarcts and normal subjects, hemispheric CMRGlu was most severely depressed in patients with bilateral thalamic lesions (29.9 ± 2.74 μmol/100 g per minute, $P = .05$ in Tukey's multiple-range test), while unilateral infarcts decreased CMRGlu in the ipsilateral hemisphere only to 32.2 ± 2.97 μmol/100 g per minute and had little effect on CMRGlu of the contralateral hemisphere (34.1 ± 3.85 μmol/100 g per minute) (Fig 1).

Effects on Regional Metabolic Rates

The dependence on infarct location of the ipsilateral pattern of metabolic depression was analyzed by ANOVA of regional differences from hemispheric mean values. There was a significant interaction between infarct location and regional metabolism ($P = .035$). Post hoc contrasts of individual regions demonstrated that the effect was most pronounced in frontal and occipital areas ($P = .007$ and $P = .054$, respectively), where medial thalamic infarcts caused the largest metabolic depression.

For detailed analysis, the profile deviation from normal control subjects of regional cortical values was plotted (Fig 2). The profile of anterior infarcts was close to normal (Fig 3). Frontal hypometabolism was most pronounced in medial infarcts (Fig 4), whereas CMRGlu in visual and mesiotemporal cortex was most severely affected in posterior thalamic infarcts (Fig 5).

In a separate analysis of subcortical

structures, noninfarcted homolateral thalamic tissue was found severely deactivated ($P = .001$), but CMRGlu in contralateral thalamus was not significantly affected. Especially in patients with larger thalamic lesions, while these values may suffer from partial volume effects not permitting a clear separation of infarcted and noninfarcted tissue, a marked decrease of thalamic CMRGlu was also observed in patients with small lesions (eg, small anterior infarct, as shown in Fig 3), which did not cause a striking effect on most cortical areas.

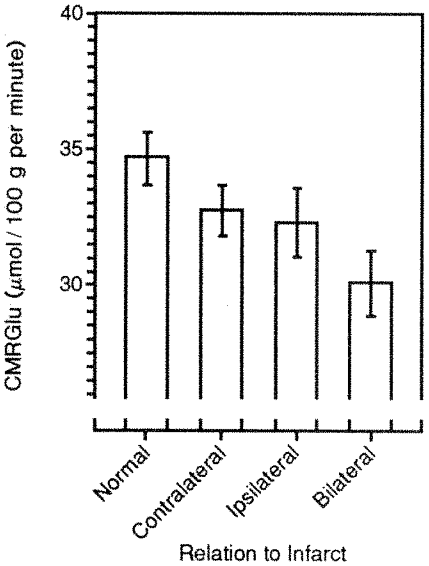

Fig 1.—Mean regional cerebral metabolic rates of glucose (CMRGlu) in hemispheres of normal volunteers (n = 11, mean of both hemispheres), in hemispheres contralateral and ipsilateral to unilateral thalamic infarcts (n = 6), and in hemispheres of patients with bilateral thalamic infarcts (n = 5, mean of both hemispheres). Error bars indicate SEM.

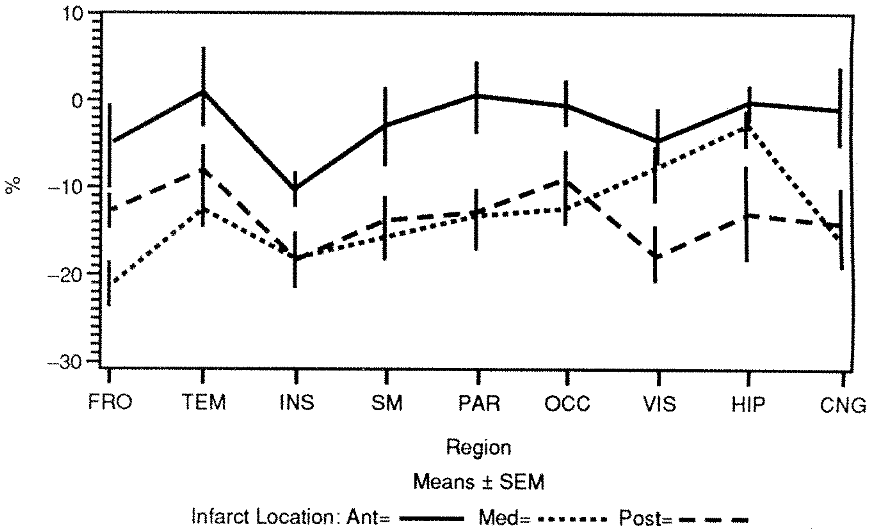

Fig 2.—Difference from normal control subjects of regional cortical cerebral metabolic rates of glucose (CMRGlu) in affected hemispheres of patients with thalamic infarcts grouped according to location of lesion. Anterior (ANT) thalamic infarcts induced little deviation from normal CMRGlu pattern; with medial (MED) infarcts, metabolic decreases were most pronounced in frontal cortex; posterior (POST) lesions had largest effect on visual cortex and hippocampal structures. FRO indicates frontal cortex; TEM, lateral temporal cortex; INS, insular cortex; SM sensorimotor cortex; PAR, parietal cortex; OCC, occipital convexity cortex; VIS, primary visual cortex; HIP, mesial temporal cortex; and CNG, cingulate cortex.

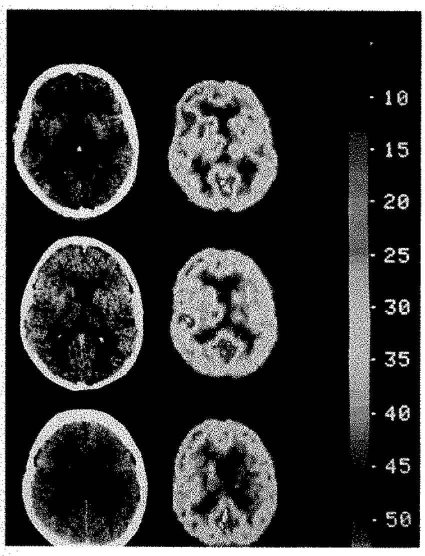

Fig 3.—Computed tomographic and (^{18}F)-2-fluoro-2-deoxy-D-glucose-positron emission tomographic images at three levels (centered around middle part of thalamus) in patient 1 with unilateral infarct in left anterior thalamus. Thalamic lesion has low glucose metabolism, but also noninfarcted thalamus is metabolically depressed. Other regional cerebral metabolic rates of glucose values are in normal range. Gray scale indicates cerebral metabolic rates of glucose values in micromoles per 100 g per minute.

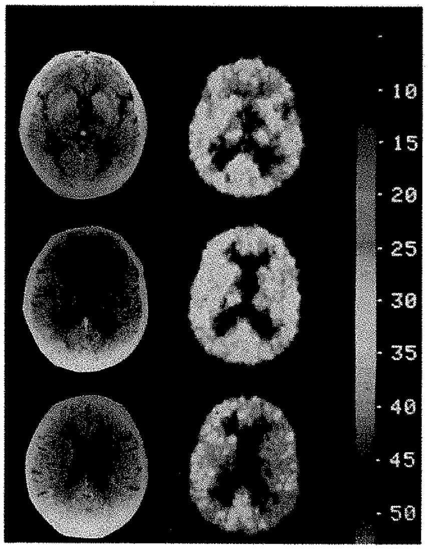

Fig 4.—Computed tomographic and (^{18}F)-2-fluoro-2-deoxy-D-glucose-positron emission tomographic images at three levels (centered around middle part of thalamus) in patient 5 with bilateral infarcts in medial thalamus. Glucose metabolism is diffusely decreased with most pronounced effects on frontal cortex. Gray scale indicates cerebral metabolic rates of glucose in micromoles per 100 g per minute.

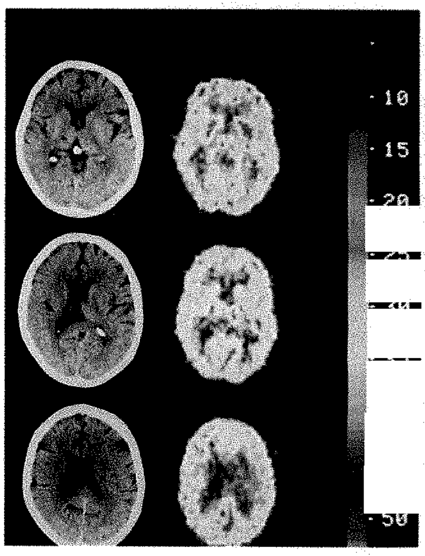

Fig 5.—Computed tomographic and (^{18}F)-2-fluoro-2-deoxy-D-glucose-positron emission tomographic images at three levels (centered around middle part of thalamus) in patient 8 with unilateral infarct in right posterior thalamus (posterolateral ventral nucleus). Regional depression of cerebral metabolic rate of glucose in occipital cortex. Gray scale indicates cerebral metabolic rates of glucose in micromoles per 100 g per minute.

Regional CMRGlu of the basal ganglia was mainly affected by lesions in the medial thalamus, while the values measured in the anterior and posterior group were only slightly below those found in the control subjects. Metabolic rates of glucose in the cerebellum were within the normal range in all but one case with a bilateral posterior infarct. Group differences were not significant.

COMMENT

The thalamus, being the most important subcortical relay center for exteroceptive and proprioceptive stimuli, plays a fundamental role in the integration and coordination of information going to the cortex, but it is also an essential part of the ascending reticular and limbic systems, and it has important connections with the basal ganglia and receives input from the cerebellum.[10] The main efferent pathways can be grouped into the following four categories[29]: (1) fibers to circumscribed and well-defined areas of the neocortex from specific relay nuclei with strict somatotropic projections; (2) fibers to the limbic system and the basal ganglia; (3) fibers projecting diffusely into most cortical areas; and (4) intrathalamic connecting fibers not leaving the thalamus.

Based on the concept of functional deactivation or activation as a metabolic indicator of impaired input to identifiable brain structures, PET can be used to follow projection systems when the nuclei where efferent fibers originate are selectively destroyed or stimulated.

This concept was successfully applied to the study of metabolic activation during simple or complex physiologic stimulation and during the performance of various tasks, thereby opening a new venue for functional neuroanatomy in the intact individual.[30-32] This approach can also be used to demonstrate the metabolic depression in areas connected to lesioned brain structures. Therefore, it may help—like degeneration studies in classical neuroanatomy—in the identification of the target region of projection systems and in the interpretation of complex clinical syndromes caused by focal tissue damage. Considering the limited spatial resolution of PET, effects on small structures, eg, the individual thalamic nuclei, where intrathalamic fibers project to can hardly be visualized, thus limiting the application of this method to large thalamic projection fields outside the thalamus. Despite these limitations, our study indicated that noninfarcted thalamic structures have decreased metabolism consequent to the lack of intrathalamic input.

Most studies so far have shown global reductions of metabolism and blood flow as a result of thalamic infarction,[12,13,16,18] while regional effects did not reach statistical significance. This conclusion, which can also be derived from a first look at our data (Table 2), emphasizes effects mediated by the diffuse projection of various thalamic nuclei—mainly the centromedian and intralaminar nuclei—to widespread cortical and subcortical areas. Therefore, the global metabolic depression was most marked in the group with medial thalamic infarctions that always involved major intralaminar nuclei. However, more detailed statistical analysis of our data suggests another interpretation that also fits to the accepted function of thalamic relay nuclei: the metabolic rate of various brain regions obviously is selectively affected by thalamic infarctions, and this selectivity depends on the location of the infarction within the thalamus. The sum of these regional effects, together with a global depression, would then cause metabolic decreases observed in the whole hemisphere. The areas of significant metabolic depression in the three infarct location groups corresponded with the main anatomical projections: The marked metabolic deactivation (20% decrease of rCMRGlu, compared with control subjects) in the frontal lobe of patients with medial thalamic infarction corresponds with the large projections of the medial thalamic nucleus to this region, while the widespread additional cortical effects are probably due to the diffuse projections originating in centromedian and other intralaminar nuclei involved in infarctions in the medial portion of the thalamus. In contrast, regional effects of posterior infarcts were most prominent in the visual, parietal, insular, and sensorimotor areas. These effects may be ascribed to the specific projections from lateral, posterior, and ventroposterior nuclei. The apparent similarity of regional effects of medial and posterior infarctions may be explained either by some involvement of diffusely projecting nuclei, or by the unprecise separation of infarct locations on CT. In contrast, anterior thalamic infarctions caused no significant regional metabolic depression despite large projections from the anterior nucleus to the cingulate gyrus. While such an effect might have escaped detection in this small group due to the limited spatial resolution, a decrease of CMRGlu in nonaffected thalamic nuclei was obvious and may have produced the clinical symptoms, eg, the memory and cognitive disturbances prominent in these cases.

Our results are also in good agreement with the hypothesis of some major involvement of efferent thalamic fibers projecting to subcortical and limbic structures: medial infarctions depress metabolism in the lentiform and caudate nuclei, since a main tract leads from the centromedian nucleus to the putamen, while more ventromedial intralaminar nuclei affect the metabolic rate in the caudate nucleus.[33] From various parts of the thalamus sizable projections lead to limbic structures (anterior nucleus-cingulate gyrus, medial nucleus-amygdaloid body, dorsolateral nucleus-hippocampus and cingulate gyrus). However, the metabolic effects on limbic structures observed in our small groups (more marked effect on cingulate gyrus with medial, and on mesial temporal and cingulate structures with posterior lesions) did not fully correspond with these connections. Obviously, the involvement of the limbic system and the deactivation of reticular nuclei additionally influences global brain metabolism by indirect mechanisms.

In two cases studied with PET during stimulation by electrodes implanted into the ventral posterior nucleus for pain treatment, global metabolism was decreased by 20% in both hemispheres, while the pattern of specific metabolic regional effects was similar to the unstimulated state.[12] This finding, which contrasts with the enhancement during stimulation observed by Katayama et al,[34] may be interpreted as corresponding with decreased anxiety due to pain relief. However, fibers diffusely projecting from thalamic nuclei to the cortex and synapsing in layer four on inhibitory Golgi II cells (stellate cells) were described,[29,35] which may mediate a widespread deactivation.

In previous investigations, some of the significant regional effects established in our group of selected patients with isolated thalamic infarctions were reported in an anecdotal way: two of the patients described by Baron et al[13] had infarcts restricted to anterior and medial nuclei, and distinct functional depression was found in frontal parietal cortex; two with posterior lesions showed temporo-occipital hypometabolism. In five of the 10 cases presented by Baron et al,[13] the infarction widely exceeded the thalamus, and this was also the case in most patients included in the other studies.[12,16,18] These mixed cohorts of patients, who, in contrast with the cases selected for this study, also presented motor or sensory deficits clearly not due to thalamic lesions, hampered the interpretation of results and weakened their statistical analysis. The finding of occasional contralateral cerebellar deactivation[12,18] may be statistically significant only in samples of larger size, or it may be related to a lesion of the internal capsule, since the thalamus has afferent but no direct efferent connections with the cerebellum. The 11 patients in our study were carefully selected to have infarctions restricted to the thalamus on CT. These patients suffered from symptoms caused exclusively by thalamic lesions, ie, dementia with prominent amnestic syndromes, Déjerine-Roussy syndrome, and language problems. In none of the patients were symptoms related to lesions in other locations present, which were reported to be part of the clinical syndrome in the other studies.[13,18]

Our study has various limitations as to the functional assessment of thalamic projections. The number of cases was small, preventing further subgrouping. The identification of individual nuclei involved in the infarct could not be achieved by CT, and magnetic resonance imaging scans were not consistently available. Therefore, only three categories—anterior, medial, and posterior infarcts—were used with some overlap in the involvement of ventral and lateral nuclei. The limited spatial resolution of PET did not permit the quantification of metabolic rates in very small brain structures and, together with the poor identification of affected nuclei on CT, prevented a clear somatotropic (point-to-point) correspondence between thalamic lesion and metabolically inactivated structures. Nevertheless, this study emphasizes the potential of PET for analyzing the effect of small lesions in the thalamus on the function of remote brain regions: For all four categories of thalamic projections,[29] typical depression of glucose metabolism due to specific thalamic lesions was evident. Therefore, our results encourage further investigations, with improved technology on larger groups of patients, to shed more light on the intricate functional anatomy of the thalamus. Especially in cases with thalamic infarction, where the extent of the lesion is not restricted to individual nuclei or groups of nuclei but is due to the complex and variable supply from the internal carotid, posterior communicating, and posterior cerebral arteries,[36] PET studies of the pattern of metabolic deactivation can afford more insight into the primarily affected structures and thereby improve diagnostic classification.

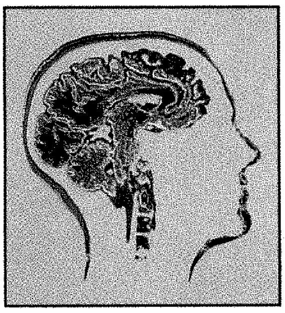
THROUGH A CALCIUM-MODULATING MECHANISM OF ACTION



CEREBROSELECTIVE

NIMOTOP®

nimodipine/Miles

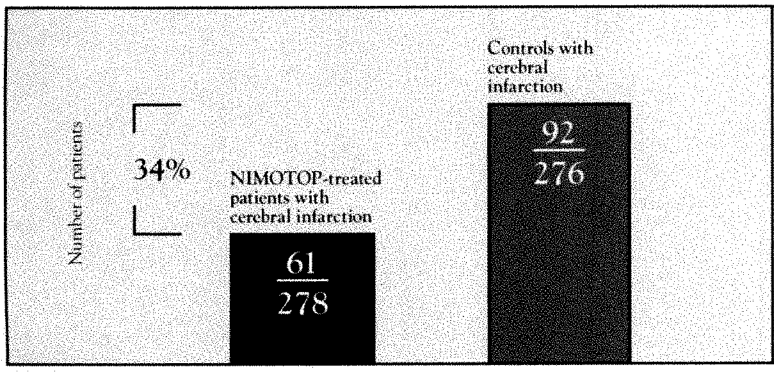
CAPSULES 30 mg

REDUCES INCIDENCE OF CEREBRAL INFARCTION IN PATIENTS FOLLOWING SUBARACHNOID HEMORRHAGE

In the largest study to date, NIMOTOP demonstrated a significant reduction in incidence of cerebral infarction[1]

- Twenty-two percent (61/278) of NIMOTOP-treated patients experienced cerebral infarction vs. 33% (92/276) of controls
- NIMOTOP reduced the incidence of cerebral infarction by 34%

Thirty-four percent reduction in incidence of cerebral infarction with NIMOTOP-treated patients vs. controls (n=554; p=0.003)[1]*



*90% of patients in this study were Hunt and Hess Grades I-III.

Dose: 60 mg (two 30 mg liquid-filled capsules) every 4 hours for 21 days commencing within 96 hours of SAH.

Adapted from Pickard, et al.[1]

NIMOTOP modulates calcium influx to promote cerebral perfusion, and may directly protect neurons[2-5]

"[In animals] The beneficial cytoprotective effect of nimodipine, probably related to normalization of calcium homeostasis and blood-brain barrier permeability after ischemia, may reflect both vascular and cellular sites of action."[6]

Lazarewicz JW, et al. *Stroke* 1989.

"[In humans] The data thus suggest that nimodipine neither prevents nor reverses cerebral vasospasm. Calcium channel blockers such as nimodipine may have an effect on cerebral arterioles that are below the limits of resolution of angiography. . . . "[1]

Pickard JD, et al. *Br Med J* 1989.

MILES

CEREBROSELECTIVE

NIMOTOP®

nimodipine/Miles

CAPSULES 30 mg

NIMOTOP REDUCES THE INCIDENCE OF CEREBRAL INFARCTION FOLLOWING SUBARACHNOID HEMORRHAGE

BRIEF SUMMARY
NIMOTOP® (nimodipine/Miles) CAPSULES
For Oral Use

INDICATIONS AND USAGE

Nimotop® (nimodipine) is indicated for the improvement of neurological deficits due to spasm following subarachnoid hemorrhage from ruptured congenital intracranial aneurysms in patients who are in good neurological condition post-ictus (e.g. Hunt and Hess Grades I-III). Oral Nimotop® therapy should begin within 96 hours of the subarachnoid hemorrhage and continue for 21 days.

CONTRAINDICATIONS

None known.

PRECAUTIONS

General: Blood Pressure: Nimodipine has the hemodynamic effects expected of a calcium channel blocker, although they are generally not marked. In patients with subarachnoid hemorrhage given Nimotop® in clinical studies, about 5% were reported to have had lowering of the blood pressure and about 1% left the study because of this (not all could be attributed to nimodipine). Nevertheless, blood pressure should be carefully monitored during treatment with Nimotop® based on its known pharmacology and the known effects of calcium channel blockers.

Hepatic Disease: The metabolism of Nimotop® is decreased in patients with impaired hepatic function. Such patients should have their blood pressure and pulse rate monitored closely and should be given a lower dose (see Dosage and Administration).

Laboratory Test Interactions: None known.

Drug Interaction: It is possible that the cardiovascular action of other calcium channel blockers could be enhanced by the addition of Nimotop®.

In Europe, Nimotop® was observed to occasionally intensify the effect of antihypertensive compounds taken concomitantly by patients suffering from hypertension: this phenomenon was not observed in North American clinical trials.

Carcinogenesis, Mutagenesis, Impairment of Fertility: In a two-year study, higher incidences of adenocarcinoma of the uterus and Leydig-cell adenoma of the testes were observed in rats given a diet containing 1800 ppm nimodipine (equivalent to 91 to 121 mg/kg/day nimodipine) than in placebo controls. The differences were not statistically significant; however, the higher rates were well within historical control range for these tumors in the Wistar strain. Nimodipine was found not to be carcinogenic in a 91-week mouse study but the high dose of 1800 ppm nimodipine-in-feed (546 to 774 mg/kg/day) shortened the life expectancy of the animals. Mutagenic studies, including the Ames, micronucleus and dominant lethal tests were negative.

Nimodipine did not impair the fertility and general reproductive performance of male and female Wistar rats following oral doses of up to 30 mg/kg/day when administered daily for more than 10 weeks in the males and 3 weeks in the females prior to mating and continued to day 7 of pregnancy. This dose in a rat is about 4 times the equivalent clinical dose of 60 mg q4h in a 50 kg patient.

Pregnancy: Pregnancy Category C. Nimodipine has been shown to have a teratogenic effect in Himalayan rabbits. Incidences of malformations and stunted fetuses were increased at oral (by gavage) doses of 1 and 10 mg/kg/day administered from day 6 through day 18 of pregnancy but not at 3.0 mg/kg/day in one of two identical rabbit studies. In the second study an increased incidence of stunted fetuses was seen at 1.0 mg/kg/day but not at higher doses. Nimodipine was embryotoxic, causing resorption and stunted growth of fetuses, in Long Evans rats at 100 mg/kg/day administered by gavage from day 6 through day 15 of pregnancy. In two other rat studies, doses of 30 mg/kg/day nimodipine administered by gavage from day 16 of gestation and continued until sacrifice (day 20 of pregnancy or day 21 post partum) were associated with higher incidences of skeletal variation, stunted fetuses and stillbirths but no malformations. There are no adequate and well controlled studies in pregnant women to directly assess the effect on human fetuses. Nimodipine should be used during pregnancy only if the potential benefit justifies the potential risk to the fetus.

Nursing Mothers: Nimodipine and/or its metabolites have been shown to appear in rat milk at concentrations much higher than in maternal plasma. It is not known whether the drug is excreted in human milk. Because many drugs are excreted in human milk, nursing mothers are advised not to breast feed their babies when taking the drug.

Pediatric Use: Safety and effectiveness in children have not been established.

ADVERSE REACTIONS

Adverse experiences were reported by 92 of 823 patients with subarachnoid hemorrhage (11.2%) who were given nimodipine. The most frequently reported adverse experience was decreased blood pressure in 4.4% of these patients. Twenty-nine of 479 (6.1%) placebo treated patients also reported adverse experiences. The events reported with a frequency greater than 1% are displayed below by dose.

DOSE q4h
Number of Patients (%)

	Nimodipine					Placebo
Sign/Symptom	**0.35 mg/kg (n = 82)**	**30 mg (n = 71)**	**60 mg (n = 494)**	**90 mg (n = 172)**	**120 mg (n = 4)**	**(n = 479)**
Decreased Blood Pressure	1 (1.2)	0	19 (3.8)	14 (8.1)	2 (50.0)	6 (1.2)
Abnormal Liver Function Test	1 (1.2)	0	2 (0.4)	1 (0.6)	0	7 (1.5)
Edema	0	0	2 (0.4)	2 (1.2)	0	3 (0.6)
Diarrhea	0	3 (4.2)	0	3 (1.7)	0	3 (0.6)
Rash	2 (2.4)	0	3 (0.6)	2 (1.2)	0	3 (0.6)
Headache	0	1 (1.4)	6 (1.2)	0	0	1 (0.2)
Gastrointestinal Symptoms	2 (2.4)	0	0	2 (1.2)	0	0
Nausea	1 (1.2)	1 (1.4)	6 (1.2)	1 (0.6)	0	0
Dyspnea	1 (1.2)	0	0	0	0	0
EKG Abnormalities	0	1 (1.4)	0	1 (0.6)	0	0
Tachycardia	0	1 (1.4)	0	0	0	0
Bradycardia	0	0	5 (1.0)	1 (0.6)	0	0
Muscle Pain/Cramp	0	1 (1.4)	1 (0.2)	1 (0.6)	0	0
Acne	0	1 (1.4)	0	0	0	0
Depression	0	1 (1.4)	0	0	0	0

There were no other adverse experiences reported by the patients who were given 0.35 mg/kg q4h, 30 mg q4h or 120 mg q4h. Adverse experiences with an incidence rate of less than 1% in the 60 mg q4h dose group were: hepatitis; itching; gastrointestinal hemorrhage; thrombocytopenia; anemia; palpitations; vomiting; flushing; diaphoresis; wheezing; phenytoin toxicity; lightheadedness; dizziness; rebound vasospasm; jaundice; hypertension; hematoma.

Adverse experiences with an incidence rate less than 1% in the 90 mg q4h dose group were: itching; gastrointestinal hemorrhage; thrombocytopenia; neurological deterioration; vomiting; diaphoresis; congestive heart failure; hyponatremia; decreasing platelet count; disseminated intravascular coagulation; deep vein thrombosis.

As can be seen from the table, side effects that appear related to nimodipine use based on increased incidence with higher dose or a higher rate compared to placebo control, included decreased blood pressure, edema and headaches which are known pharmacologic actions of calcium channel blockers. It must be noted, however, that SAH is frequently accompanied by alterations in consciousness which lead to an under reporting of adverse experiences. Patients who received nimodipine in clinical trials for other indications reported flushing (2.1%), headache (4.1%) and fluid retention (0.3%), typical responses to calcium channel blockers. As a calcium channel blocker, nimodipine may have the potential to exacerbate heart failure in susceptible patients or to interfere with A-V conduction, but these events were not observed.

No clinically significant effects on hematologic factors, renal or hepatic function or carbohydrate metabolism have been causally associated with oral nimodipine. Isolated cases of non-fasting elevated serum glucose levels (0.8%), elevated LDH levels (0.4%), decreased platelet counts (0.3%), elevated alkaline phosphatase levels (0.2%) and elevated SGPT levels (0.2%) have been reported rarely.

OVERDOSAGE

There have been no reports of overdosage from the oral administration of Nimotop®. Symptoms of overdosage would be expected to be related to cardiovascular effects such as excessive peripheral vasodilation with marked systemic hypotension. Clinically significant hypotension due to Nimotop® overdosage may require active cardiovascular support. Norepinephrine or dopamine may be helpful in restoring blood pressure. Since Nimotop® is highly protein-bound, dialysis is not likely to be of benefit.

DOSAGE AND ADMINISTRATION

Nimotop® is given orally in the form of ivory colored, soft gelatin 30 mg capsules for subarachnoid hemorrhage.

The oral dose is 60 mg (two 30 mg capsules) every 4 hours for 21 consecutive days. Oral Nimotop® therapy should commence within 96 hours of the subarachnoid hemorrhage.

If the capsule cannot be swallowed, e.g., at the time of surgery, or if the patient is unconscious, a hole should be made in both ends of the capsule with an 18 gauge needle, and the contents of the capsule extracted into a syringe. The contents should then be emptied into the patient's *in situ* naso-gastric tube and washed down the tube with 30 mL of normal saline (0.9%).

Patients with hepatic failure have substantially reduced clearance and approximately doubled C_{max}. Dosage should be reduced to 30 mg every 4 hours, with close monitoring of blood pressure and heart rate.

Spectral Analysis of Heart Rate in Diabetic Autonomic Neuropathy

A Comparison With Standard Tests of Autonomic Function

Roy Freeman, MD; J. Philip Saul, MD; Mark S. Roberts, MD, MPP; Ronald D. Berger, MD, PhD;
Christopher Broadbridge; Richard J. Cohen, MD, PhD

• Power spectral analysis of the heart rate was compared with standard tests of autonomic function performed on 15 insulin-dependent diabetic patients with symptoms of autonomic dysfunction. The high-frequency power, low-frequency power, and total power of the heart rate power spectrum measured in the supine position—possible measures of parasympathetic nervous system function—were significant predictors of the expiratory-inspiratory ratio, the beat-to-beat heart rate difference on deep respiration, the standard deviation of the resting heart rate, the 30:15 ratio, and the Valsalva ratio. The change in low-frequency power on moving from the supine to upright position, a possible measure of sympathetic nervous system function, was a modest predictor of the systolic and diastolic blood pressure fall in response to postural change, but a poor predictor of the blood pressure response to isometric exercise and a cold stimulus. This study supports the role of heart rate power spectral analysis as a clinical test of autonomic function in patients with known or suspected autonomic failure.

(*Arch Neurol.* 1991;48:185-190)

Autonomic neuropathy is a frequent complication of diabetes and has a wide range of clinical presentations.[1] Although there is no gold-standard measure of autonomic dysfunction, over the past 15 years, several tests assessing cardiovascular autonomic function have been described. These include measures of heart rate variation, baroreceptor function, and cardiovascular responsivity to postural change, cold pressor, and exercise.[2] These tests have been criticized as being insensitive to early changes in autonomic function, particularly sympathetic nervous system dysfunction.[3] They also require active patient participation, which is difficult to standardize. Power spectral analysis of the resting heart rate has recently been introduced as a test of autonomic function. This technique may answer these criticisms and may provide an accurate, sensitive, and specific single test of autonomic function, measuring both parasympathetic and sympathetic divisions of the autonomic nervous system and requiring minimal patient cooperation. Prior to the widespread introduction of power spectral analysis as a measure of autonomic function, it is important to compare this technique with the standard tests of autonomic function.

Spectral analysis reduces a signal to the sum of its component sine waves of different amplitudes and frequencies. The power spectrum displays the squared amplitude of these sine waves as a function of frequency, thus expressing the variance as a function of frequency. Heart rate fluctuations, which reflect modulation of sinus node activity by autonomic and other homeostatic mechanisms, can be quantified and displayed using this technique. Power spectral analysis may thus provide a useful noninvasive technique for analyzing the autonomic mechanisms that control heart rate.[4]

Spectral analysis of the resting heart rate commonly produces several prominent peaks (Fig 1). The peak found at the highest frequency (greater than 0.15 Hz) reflects oscillations of heart rate that occur with respiration—the respiratory sinus arrhythmia.[4,5] Quantification of these oscillations provides a measure of the response of the sinus node to fluctuations in vagal nerve activity at the respiratory frequency and is reduced by parasympathetic pharmacological blockade.[5] Oscillations in heart rate at frequencies less than 0.15 Hz are mediated by both the vagus and the cardiac sympathetic nerves. Spectral power within the 0.05- to 0.15-Hz frequency band most likely represents baroreceptor feedback activity, while the spectral power at less than 0.05 Hz may reflect both cardiac autonomic input as well as the influence of circulating catecholamines.[6,7] In normal subjects, the move from the supine to upright position produces a shift in the power spectrum from high to low frequencies (Fig 1). This shift in spectral power, induced by a postural change, is reduced by β-adrenergic receptor blockade and may provide an index of sympathetic activity.[5]

In this study, we performed spectral analysis of the heart rate and standard tests of autonomic function on 15 insulin-dependent diabetic patients with symptoms of autonomic dysfunction, in order to compare indexes derived from the heart rate-power spectrum with the range of values occurring with standard tests performed on patients with suspected autonomic dys-

function. To our knowledge, no study to date has compared spectral analysis with individual tests of autonomic function.

PATIENTS AND METHODS

Fifteen insulin-dependent diabetic patients with symptoms of autonomic dysfunction had standard tests of autonomic function and spectral analysis of the heart rate performed. The mean age was 41.1 ± 20.0 years, with a mean duration of diabetes of 10.9 ± 8.7 years. All testing was carried out in the Autonomic Evaluation Unit of the New England Deaconess Hospital, Boston, Mass. Blood pressure was measured with a noninvasive vital sign monitor (Critikon Dinamap 1846SX/P, Tampa, Fla) connected to an IBM personal computer AT via an RS232 serial interface board. Heart rate for standard tests of autonomic function was measured by an electrocardiographic monitor (Hewlett-Packard, model 78203A, Waltham, Mass), connected to the microcomputer via a data acquisition board (MetraByte Dash-8). The time interval between two successive R waves detected by the electrocardiographic monitor was translated to heart rate and recorded by the microcomputer in real time.

Patients were given sufficient time to attain baseline autonomic function. Basal state measurements (systolic blood pressure, diastolic blood pressure, mean arterial blood pressure, and heart rate) were obtained in the supine position.

Standard Autonomic Test Methods

Heart Rate Variation at Rest.—The SD of 150 consecutive R-R intervals, recorded while the subject lay quietly breathing, was calculated.[8,9]

Heart Rate Variation With Respiration.—Patients were trained to breathe at the rate of six breaths per minute in the sitting position. The ratio of the six longest to the six shortest R-R intervals was determined (expiratory-inspiratory [E-I] ratio).[10] The difference between the maximum and minimum heart rates (Max − Min) was calculated.[11]

The Valsalva Maneuver.—The seated patient was asked to expire for 15 to 20 seconds against a resistance of 40 mm Hg in an open loop system. The Valsalva ratio, the ratio of the maximum heart rate during the expiratory phase to the minimum heart rate during the relaxation phase, was calculated.[12]

The Cold Pressor Test.—The increase in systolic blood pressure after the patient placed his/her hand in cold water (4°C) for 60 seconds was determined.[13]

Isometric Exercise.—The patient was instructed to squeeze a handgrip dynamometer at 30% of his maximal effort for 4 minutes. Careful attention was paid to ensure adequate effort by all patients. The increase in diastolic blood pressure was determined.[14]

The Hemodynamic Response to Tilt Table Testing.—The blood pressure and heart rate were measured over 5 minutes following passive tilting to 60°. The change in heart rate, systolic blood pressure, diastolic blood pressure, and mean arterial pressure, was recorded.[15]

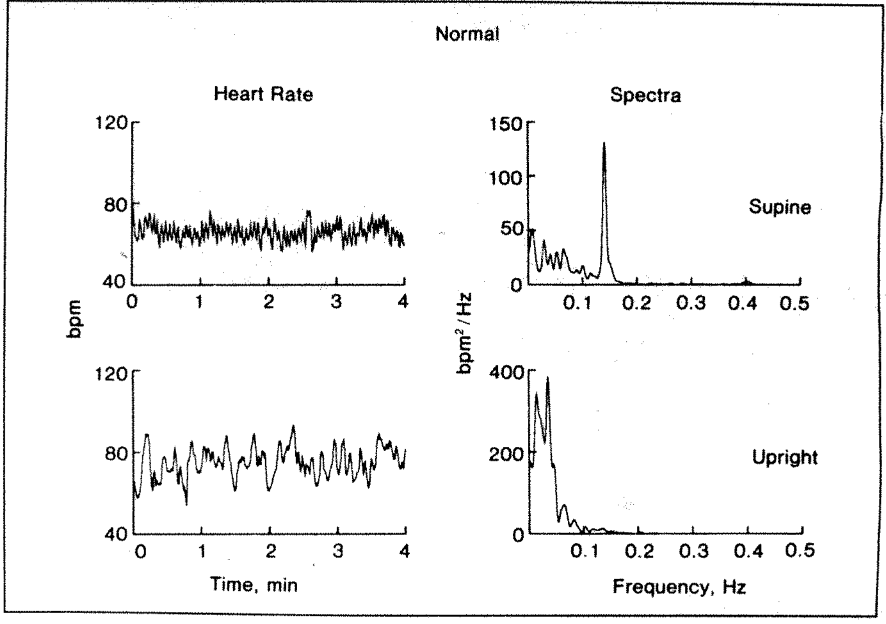

Fig 1.—The power spectrum of the normal resting heart rate. bpm indicates beats per minute.

Table 1.—Summary of Standard Autonomic Test and Spectral Analysis Results*

	Mean	Range	Control Mean
Standard deviation	2.16 ± 1.4	0.6-4.9	4.2 ± 1.3
E-I ratio	1.15 ± 0.16	1.02-1.56	1.4 ± 0.19
Max − min heart rate	14.1 ± 8.5	4.1-27.6	27.9 ± 9.96
30:15 ratio	1.05 ± 0.11	0.93-1.3	1.19 ± 0.18
Valsalva ratio	1.27 ± 0.29	1.0-2.0	1.54 ± 0.33
Cold pressor	19.29 ± 9.13	5.0-35.0	22.8 ± 20.16
Isometric exercise	9.6 ± 9.9	−6.0-30.0	14.2 ± 11.4
Systolic blood pressure change	−26.8 ± 25.8	−87.0-10.0	−1.6 ± 10.3
Supine low-frequency power	4.35 ± 7.4	0.07-26.6	9.05 ± 8.58
Supine high-frequency power	2.32 ± 4.18	0.05-15.04	3.75 ± 2.90
Supine total power	8.16 ± 13.38	0.21-46.48	16.38 ± 14.05
Tilt low-frequency power	7.35 ± 13.5	0.03-49.55	18.39 ± 8.3

*Results are expressed as mean ± SD. Laboratory control values are included for comparison purposes. E-I indicates expiratory-inspiratory.

The Hemodynamic Response to Standing.—Blood pressure change and heart rate were measured for 5 minutes after active standing. The change in heart rate, systolic blood pressure, diastolic blood pressure, and mean arterial pressure was recorded.[16] The ratio of the longest R-R interval at around the 30th beat to the shortest R-R interval around the 15th beat after active standing was calculated (30:15 ratio).[16]

Specially designed and validated software computed the measurements and ratios described above, and stored all data.

Spectral Analysis Methods

A surface lead of the electrocardiogram was recorded on magnetic tape during spontaneous respiration in the supine and upright positions following passive tilting to 60° on an electrically driven tilt table. After anti-alias filtering, the electrocardiogram was sampled off line at 360 Hz. R-waves were detected, and a smoothed instantaneous heart rate time series was formed at 3 Hz, as previously described.[17] One 3-minute (171 seconds = 512 points) segment of data from each position was chosen for power spectral analysis, which was performed using the Blackman-Tukey method.[18]

The power spectra were quantified by the area (power) in two frequency bands: low-frequency power from 0.02 to 0.15 Hz, and high-frequency power from 0.15 to 1.0 Hz. The fractional power in each band was also computed as a percentage of the total power. Traditional tests predominantly measuring parasympathetic nervous system function were compared with supine, total power, supine high-frequency power, and supine low-frequency power. Traditional tests, predominantly measuring sympathetic nervous system function, were compared with the change in low-frequency power on moving from a supine to an upright position.

Statistical Methods

Multiple linear regression was used to predict standard autonomic test results as a function of age, duration of diabetes, and a spectral analysis index chosen as described above. Independent variables were considered significant if $P < .05$. The following regression equation was used: Autonomic Test Result=Constant+β_1 Spectral Index+β_2 Patient Age+β_3 Duration of Diabetes, where β_i represents the respective coefficients estimated by linear regression. Calculations were made using the SYSTAT Statistical Package (Systat Inc, Evanston, Ill).

RESULTS

Autonomic Tests and Spectral Analysis

The mean, SDs, and range of values obtained on the individual autonomic tests and spectral analysis are displayed in Table 1. For comparison purposes, we have included in this table healthy control subject values for the standard autonomic tests (age and sex matched) and spectral indexes (age range, 28 to 79 years; median age, 54 years).

Power Spectra

A normal power spectrum is displayed in Fig 1, and examples from our case material are displayed in Figs 2 and 3. In Fig 2, showing the power spectrum of a diabetic patient with moderate neuropathy, the decrease in power in both the high and low frequencies is seen in the supine position. The loss of power in all frequencies is noted in Fig 3 showing the power spectrum of the diabetic patient with severe autonomic neuropathy.

Tests of Parasympathetic Function

Supine high-frequency power, supine low-frequency power, and supine total power were significant predictors of the E-I ratio, the Max − Min, the SD, the 30:15 ratio, and the Valsalva ratio. When used in a regression equation in conjunction with the patient's age and duration of diabetes, these spectral indexes predicted a large percentage of the variation in test results (R^2 values between 0.64 and 0.92) (Tables 2 through 4). Patient age was only a significant predictor of the Max − Min and the 30:15 ratio.

This is graphically displayed in Fig 4, where the observed autonomic test result is plotted against the autonomic test result predicted by the regression equation. In this figure, a test with perfect prediction would result in all points lying along a 45° line. Conversely, a test with no predictive value would always yield the mean of the observed sample.

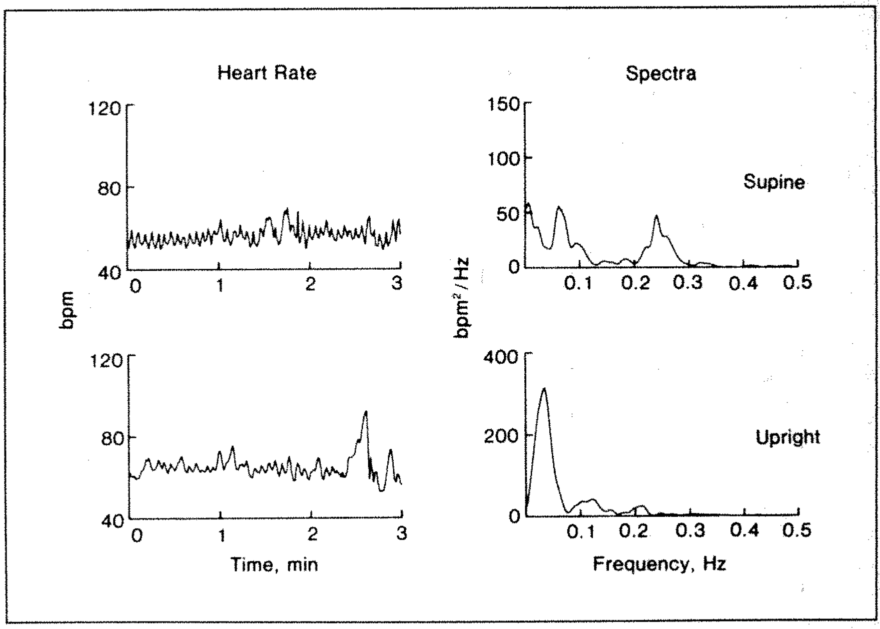

Fig 2.—The power spectrum of the resting heart rate of a diabetic patient with moderate autonomic dysfunction. bpm indicates beats per minute.

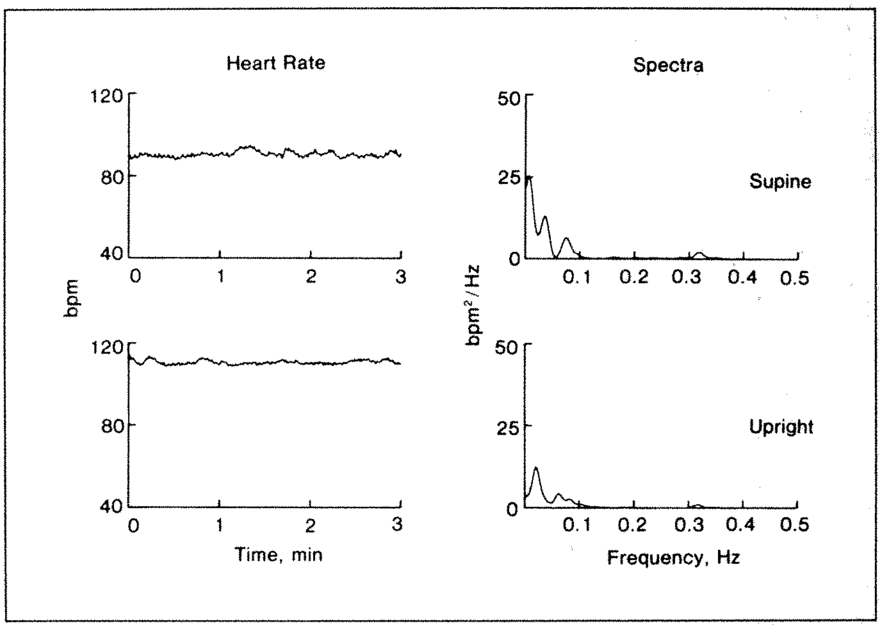

Fig 3.—The power spectrum of the resting heart rate of a diabetic patient with severe autonomic dysfunction. bpm indicates beats per minute. Note the lower *y*-axis scale of the power spectrum.

Tests of Sympathetic Function

The change in low-frequency power on moving from a supine to an upright position, when used in the above regression equation, was a modest predictor of the systolic and diastolic blood pressure fall in response to a postural change. It was a poor predictor of the blood pressure response to isometric exercise and a cold stimulus. Patient age was only a significant predictor of the blood pressure response to isometric exercise (Table 5). The graphic display of the observed autonomic test result plotted against the autonomic test result predicted by the regression equation is shown in Fig 4.

COMMENT

Autonomic dysfunction is a well-documented complication of diabetes presenting with symptoms such as orthostatic hypotension, gastroparesis, impotence, and bowel and bladder dysfunction.[1] The significant associated mortality and morbidity due to silent myocardial ischemia,[19] sudden cardiac death,[20] renal disease,[21] and anesthetic complications[22] emphasize the need for accurate, sensitive, and specific tests of autonomic function.

The standard tests described above provide an indirect measure of autonomic function. Although the physiology of these tests is complex and involves considerable interplay between efferent and afferent divisions of the parasympathetic and sympathetic nervous system, many of these tests are thought to reflect the afferent response to one specific division of the autonomic nervous system. For example, tests of heart rate variation (SD, E-I ratio, and Max − Min), the 30:15

ratio, and the Valsalva ratio are regarded predominantly as measures of the parasympathetic nervous system, while the blood pressure response to postural change, exercise, and cold are believed to predominantly reflect activity of the sympathetic nervous system.[2] Recent publications have drawn attention to the insensitivity of these tests to early alterations in sympathetic function.[3] Furthermore, the need for active patient participation, that is often unstandardized, decreases the reproducibility of these tests.

This study on a group of diabetic subjects with symptoms of autonomic dysfunction supports the use of spectral analysis of heart rate as a measure of autonomic function across the range of values associated with autonomic failure. Earlier reports have characterized the power spectrum of heart rate variation in animals,[4] normal human subjects,[5] and patients with congestive heart failure,[21] near-miss sudden infant death syndrome,[23] sudden cardiac death,[24] cardiac transplants,[25] and acute myocardial infarction.[26] In a group of diabetic subjects, Lishner et al[27] demonstrated a decline in power in all frequency ranges in comparison with those of control subjects. Pagani et al[28] demonstrated reduced R-R variance at rest and a significant difference between the increase in low-frequency power and decrease in high-frequency power in response to tilt in a group of diabetic patients compared with control subjects. These studies included only small numbers of patients with signs or symptoms of autonomic dysfunction and did not compare spectral analysis with individual tests of autonomic function.

Prior works[5-7] have demonstrated that vagus nerve activity mediates low-frequency power, high-frequency power, and total power, particularly in the supine position. We, therefore, regarded those supine spectral indexes as measures of parasympathetic function and compared them with traditional tests of the parasympathetic nervous system. In this study, those spectral indexes were significant predictors of the tests of heart rate variation measuring parasympathetic cardiac function. These tests included the standard deviation of heart rate—a measure of the spread around the mean heart rate, and the Max − Min and E-I ratio—measures of the amplitude of the heart rate variation during controlled respiration. Our results are consistent with prior works[5-7] delineating the role of the vagus nerve as a mediator of oscillations in heart rate in both high- and low-frequency bands and support the use of spectral analysis as a test of parasympathetic nervous system function in this population group.

Power in the low-frequency band forms the dominant component of the heart rate power spectrum in standing subjects,[5,28] following acute hemorrhage,[29] in patients with congestive heart failure,[23] and in patients after recent myocardial infarction.[27] These are all states associated with an increase in sympathetic outflow to the sinus node. Furthermore, the move from the supine to the upright position, which is associated with increased sympathetic nervous system outflow,[30] produces a shift in spectral power from high- to low-frequency bands. This shift in spectral power is reduced by β-adrenergic receptor blockade.[5] We, therefore, used the change in low-frequency spectral power occurring after tilting as an index of sympathetic nervous system activity. The change in low-frequency power on moving from supine to upright position was a modest predictor of the blood pressure fall in response to postural change. The change in low-frequency power was not a significant predictor of the blood pressure response to isometric exercise or to a cold stimulus. This, however, may be a reflection of the insensitivity or inaccuracy of the traditional tests themselves. It is of interest in this regard that patient age was a significant predictor of the isometric exercise test result (Table 5).

The cardiovascular physiology brought into play in response to a Valsalva maneuver or an active postural change involves a complex interplay between muscular activity, low- and high-pressure baroreceptors, the sympathetic nervous system efferents to the peripheral vascular tree, and the parasympathetic cardiac efferents.[30,31] Nevertheless, the Valsalva ratio and the 30:15 ratio (a measure of the heart rate response to postural change) are regarded primarily as indexes of parasympathetic cardiac function. These ratios are a measure of the sequential heart rate response to specific physiological perturbations, although they do not measure beat-to-beat heart rate variation. In our study, those ratios correlated strongly with spectral indexes measuring parasympathetic function and those indexes were able to accurately predict the Valsalva ratio and 30:15 ratio test results. The change in low-frequency power, a proposed measure of sympathetic nervous system function, was not a significant predictor of the Valsalva ratio and 30:15 ratio in this diseased population. Regressions using multiple spectral measures were attempted in order to incorporate the potential influence of both the sympathetic and parasympathetic nervous system on these test results (Fig 4). None of these regression equations were significantly superior predictors of autonomic test results to the regression equations containing a single spectral measure.

There is no single accepted gold-standard measure of autonomic dysfunction, although in recent years a battery of tests has gained widespread acceptance in assessing the autonomic nervous system. Without such a standard, the direct comparison between two different tests is of limited value since there is no reliable way of assessing which result is correct when the tests disagree. Discordance in test results may reflect lack of accuracy in either test. However, assuming that the standard test result correlates with the underlying disease process being measured, then, as a minimal criterion of value, the new test should correlate with the standard test. This study, comparing power spectral analysis with standard tests of autonomic function, provides support for the use of heart rate spectral analysis as a clinical test of autonomic function in patients with known or suspected autonomic dysfunction. Spectral indexes correlated strongly with, and were significant predictors of, several traditional tests of autonomic nervous system function. The minimal patient cooperation required to carry out this test and the possibility of deriving indexes of both sympathetic and parasympathetic nervous system functions from a single test may well outweigh the fact that sophisticated (but increasingly available) computer techniques are required to perform spectral analysis.

This study was supported, in part, by grant R01-HL39291 from the National Institutes of Health, grant FD-R-000393 from the Public Health Service, and a grant from the Arnold Center, Boston, Mass. J. P. Saul, MD, is a recipient of a clinical investigator award of the National Institutes of Health.

The authors acknowledge the technical expertise provided by Jason Harry, PhD, and the manuscript preparation by Christine McNulty.

The American Neurological Association

The American Neurological Association Call for Papers

The 116th Annual Meeting of the American Neurological Association will be held at the Sheraton Hotel, Seattle, Washington, beginning at 8:30 AM Monday, September 30, and ending at 1:00 PM Wednesday, October 2, 1991.

1. Authors need not be members of the American Neurological Association nor be sponsored by a member. All are welcome to submit abstracts. Acceptance will be based entirely upon quality, without consideration as to status of membership in the ANA or type of presentation. Poster sessions will be expanded; therefore posters are encouraged.
2. An abstract, not exceeding 200 words in length, double-spaced, should be submitted to the Program Chairman. *Deadline for receipt of abstracts is March 1, 1991.* Please spell out all abbreviated terms at first use or, if many abbreviations are used, attach a separate sheet listing spelled-out abbreviations. No continuation page, illustrations, or tables are to be included. An original and 10 copies must be submitted. Abstracts must report work not presented or published prior to the meeting. Additional forms may be photocopied.
3. Abstracts are solicited on the following topics:
   A. Behavioral Neurology
   B. Cerebrovascular Disease
   C. Dementia and Aging
   D. Degenerative Diseases
   E. Epilepsy
   F. Headache and Pain
   G. Movement Disorders
   H. Neuromuscular Disease
   I. Neuroscience
   J. Neuroimmunology
   K. Neurooncology
   L. Neuroophthalmology
   M. Neuropharmacology
   N. Pediatric Neurology
   O. Rehabilitation, Regeneration and Recovery
   P. Neurovirology
   Q. Trauma/Injury
   R. Other

   Authors are asked to indicate the specific topic in the box provided on the abstract form. Please use the *letter* designation.
4. The time allowed for presentations from the platform and posters may vary according to the material presented and needs of the session. Authors will be notified by the chairperson.
5. *Annals of Neurology* is the official journal of the American Neurological Association. All papers presented at the annual meeting must be submitted to the Editor for consideration by the Editorial Board of the *Annals*. Authors not wishing to have their papers considered by the *Annals* must obtain a release in writing from the Editor before submitting them for publication elsewhere.

Send abstracts and correspondence to:

Chairman, Scientific Program Committee

INJECTION

THE CASE: Four years after a radical mastectomy and chemotherapy treatment for breast carcinoma, a 63-year-old female presented with deep vein thrombosis. Metastatic spread to the brain had to be ruled out before anticoagulation therapy could be initiated.

CT DID NOT SHOW IT CLEARLY ENOUGH

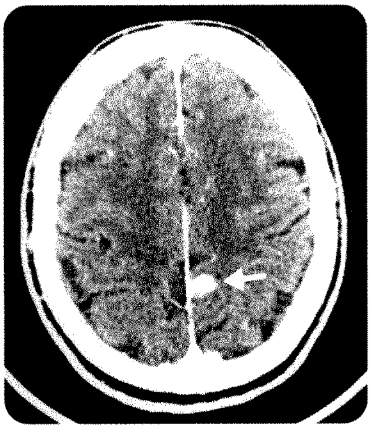

Figure 1. Contrast CT scan shows a circumscribed lesion in left parasagittal region (arrow), consistent with either metastasis or meningioma.

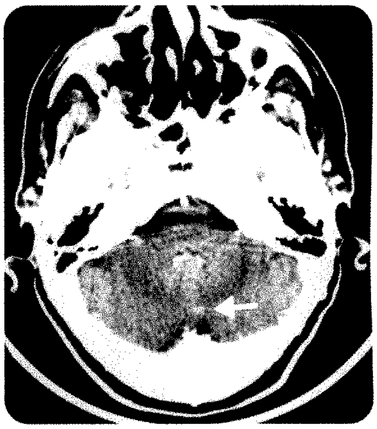

Figure 2. Contrast CT scan through posterior fossa suggests punctate area of contrast uptake in the vermis (arrow).

MRI ALONE WAS NOT DIAGNOSTIC

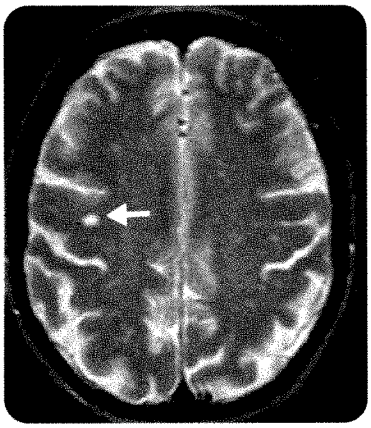

Figure 3. T2-weighted (TR 2000/TE 80) image shows area of high signal intensity in right frontoparietal region (arrow). Differential considerations include metastasis, small infarct, and demyelination. The lesion in left parasagittal region, seen in Figure 1, is not visualized.

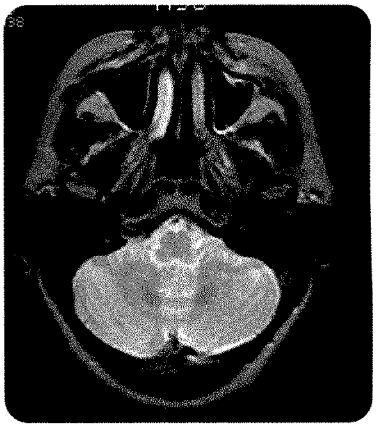

Figure 4. T2-weighted (TR 2000/TE 80) image through posterior fossa shows no abnormalities.

MAGNEVIST® INJECTION: A CRITICAL STEP IN DETECTING BRAIN METASTASES

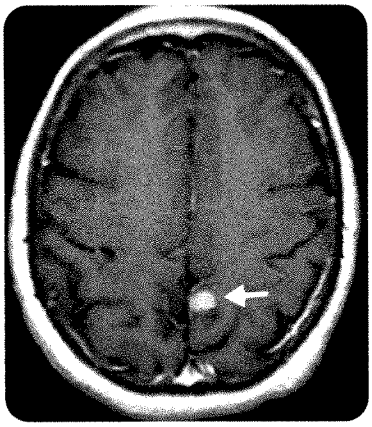

Figure 5. T1-weighted (TR 600/TE 30) image after MAGNEVIST® injection shows an enhancing lesion in left parasagittal region (arrow), as in Figure 1. The high-signal intensity lesion seen in Figure 3 does not enhance. This finding is consistent with chronic small-vessel ischemic disease, not with metastatic disease.

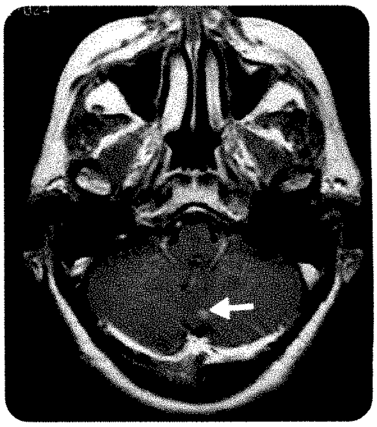

Figure 6. T1-weighted (TR 600/TE 30) enhanced image taken through posterior fossa shows well-delineated lesion in the inferior aspect of the vermis (arrow). Lesion was not clearly appreciated on unenhanced MRI or contrast CT studies.

☐ INCREASES DETECTION OF INTRACRANIAL LESIONS

May detect additional and often smaller lesions than seen with either contrast-enhanced CT or unenhanced T2-weighted images[1,2]

☐ DETECTION OF ADDITIONAL LESIONS MAY ALTER THERAPY

MAGNEVIST® injection can increase the radiologic suspicion of metastatic disease, reveal locations more favorable for biopsy, prompt the search for a primary tumor, and modify therapeutic objectives and methods[3]

BETTER MEDICINE THROUGH BETTER IMAGES

BERLEX
IMAGING®

Please see brief summary of prescribing information for MAGNEVIST® injection on last page of this advertisement.

Well tolerated[4] In clinical trials, the most common adverse reactions reported were headache (8.7%) and injection-site coldness/localized coldness (4.8%). The majority of headaches were transient and of mild to moderate severity. In clinical trials, 15% to 30% of patients experienced an asymptomatic transient rise in serum iron; hypotension and anaphylactoid reactions have occurred in less than 1% of the patients. The safety of MAGNEVIST® injection in patients with hemolytic disorders has not been studied.

BRIEF SUMMARY

INDICATIONS AND USAGE

MAGNEVIST® Injection is indicated for use with magnetic resonance imaging (MRI) in adults and children (2 years of age and older) to provide contrast enhancement in those intracranial lesions with abnormal vascularity or those thought to cause an abnormality in the blood-brain barrier. MAGNEVIST® Injection has been shown to facilitate visualization of intracranial lesions including but not limited to tumors.

MAGNEVIST® Injection is also indicated for use with MRI in adults and children (2 years of age and older) to provide contrast enhancement and facilitate visualization of lesions in the spine and associated tissues. There is, however, only limited clinical experience in children for this indication.

CONTRAINDICATIONS

None known.

WARNINGS

The accepted safety considerations and procedures that are required for magnetic resonance imaging are applicable when MAGNEVIST® Injection is used for contrast enhancement. In addition, deoxygenated sickle erythrocytes have been shown in *in vitro* studies to align perpendicular to a magnetic field which may result in vaso-occlusive complications *in vivo*. The enhancement of magnetic moment by gadopentetate dimeglumine may possibly potentiate sickle erythrocyte alignment. MAGNEVIST® Injection in patients with sickle cell anemia and other hemoglobinopathies has not been studied.

Patients with other hemolytic anemias have not been adequately evaluated following administration of MAGNEVIST® Injection to exclude the possibility of increased hemolysis.

Hypotension may occur in some patients after injection of MAGNEVIST® Injection. In clinical trials two cases were reported and in addition, there was one case of a vasovagal reaction and two cases of pallor with dizziness, sweating and nausea in one and substernal pain and flushing in the other. These were reported within 25 to 85 minutes after injection except for the vasovagal reaction which was described as mild by the patient and occurred after 6-1/2 hours. In a study in normal volunteers one subject experienced syncope after arising from a sitting position two hours after administration of the drug. Although the relationship of gadopentetate dimeglumine to these events is uncertain, patients should be observed for several hours after drug administration.

Magnevist®
(gadopentetate
dimeglumine 469.01 mg/mL)
INJECTION

PRECAUTIONS - General

Diagnostic procedures that involve the use of contrast agents should be carried out under direction of a physician with the prerequisite training and a thorough knowledge of the procedure to be performed.

In a patient with a history of grand mal seizures, MAGNEVIST® Injection was reported to induce such a seizure.

Since gadopentetate dimeglumine is cleared from the body by glomerular filtration, caution should be exercised in patients with severely impaired renal function.

The possibility of a reaction, including serious, life-threatening, fatal, anaphylactoid or cardiovascular reactions or other idiosyncratic reactions should always be considered (see ADVERSE REACTIONS) especially in those patients with a known clinical hypersensitivity.

Animal studies suggest that gadopentetate dimeglumine may alter red cell membrane morphology resulting in a slight degree of extravascular (splenic) hemolysis. In clinical trials 15-30% of the patients experienced an asymptomatic transient rise in serum iron. Serum bilirubin levels were slightly elevated in approximately 3.4% of patients. Levels generally returned to baseline within 24 to 48 hours. Hematocrit and red blood cell count were unaffected and liver enzymes were not elevated in these patients. While the effects of gadopentetate dimeglumine on serum iron and bilirubin have not been associated with clinical manifestations, the effect of the drug in patients with hepatic disease is not known and caution is therefore advised.

When MAGNEVIST® Injection is to be injected using plastic disposable syringes, the contrast medium should be drawn into the syringe and used immediately.

If nondisposable equipment is used, scrupulous care should be taken to prevent residual contamination with traces of cleansing agents.

Repeat Procedures: If in the clinical judgment of the physician sequential or repeat examinations are required, a suitable interval of time between administrations should be observed to allow for normal clearance of the drug from the body.

Information for Patients:

Patients receiving MAGNEVIST® Injection should be instructed to:

1. Inform your physician if you are pregnant or breast feeding.
2. Inform your physician if you have anemia or any diseases that affect red blood cells.

LABORATORY TEST FINDINGS

Transitory changes in serum iron and bilirubin levels have been reported in patients with normal and abnormal liver function (See PRECAUTIONS - General).

CARCINOGENESIS, MUTAGENESIS, AND IMPAIRMENT OF FERTILITY

No animal studies have been performed to evaluate the carcinogenic potential of gadopentetate dimeglumine.

Gadopentetate dimeglumine did not evoke any evidence of mutagenic potential in the Ames test (histidine-dependent *Salmonella typhimurium*) nor in a reverse mutation assay using tryptophan-dependent *Escherichia coli*. Gadopentetate dimeglumine did not induce a positive response in the (C3H 10T1/2) mouse embryo fibroblast cellular transformation assay, nor did it induce unscheduled DNA repair synthesis in primary cultures of rat hepatocytes at concentrations up to 5000 μg/mL. However, the drug did show some evidence of mutagenic potential *in vivo* in the mouse dominant lethal assay at doses of 6 mmol/kg, but did not show any such potential in the mouse and dog micronucleus tests at intravenous doses of 9 mmol/kg and 2.5 mmol/kg, respectively.

The results of a reproductive study in rats showed that gadopentetate dimeglumine when administered in daily doses of 0.1-2.5 mmol/kg, did not cause a significant change in the pregnancy rate in comparison to a control group. However, suppression of body weight gain and food consumption and a decrease in the mean weights of testis and epididymis occurred in male rats at the 2.5 mmol/kg dose. In female rats a decrease in the number of corpora lutea at the 0.1 mmol/kg dose and the suppression of body weight gain and food consumption at the 2.5 mmol/kg dose were observed.

In a separate experiment, 16 daily intravenous injections were administered to male rats. At a dose of 5 mmol/kg of gadopentetate dimeglumine, spermatogenic cell atrophy was observed. This atrophy was not reversed within a 16-day observation period following the discontinuation of the drug. This effect was not observed at a dose of 2.5 mmol/kg.

PREGNANCY CATEGORY C.

Gadopentetate dimeglumine has been shown to retard development slightly in rats when given in doses 2.5 times the human dose, and in rabbits when given in doses of 7.5 and 12.5 times the human dose. The drug did not exhibit this effect in rabbits when given in doses 2.5 times the human dose. No congenital anomalies were noted in either species.

There are no adequate and well-controlled studies in pregnant women. MAGNEVIST® Injection should be used during pregnancy only if the potential benefit justifies the potential risk to the fetus.

NURSING MOTHERS

C^{14} labelled gadopentetate dimeglumine was administered intravenously to lactating rats at a dose of 0.5 mmol/kg. Less than 0.2% of the total dose was transferred to the neonate via the milk during the 24-hour evaluation period. It is not known to what extent MAGNEVIST® Injection is excreted in human milk. Because many drugs are excreted in human milk, caution should be exercised when the drug is administered to a nursing mother and consideration should be given to temporarily discontinuing nursing.

PEDIATRIC USE

Safety and efficacy in children under the age of 2 years have not been established. (See Indications and Usage and Dosage and Administration sections).

ADVERSE REACTIONS

The most commonly noted adverse experience is headache with an incidence of 8.7%. The majority of headaches are transient and of mild to moderate severity. In 42.3% of the cases it was felt that the headaches were not related to MAGNEVIST® Injection. Injection site coldness/localized coldness is the second most common adverse experience at 4.8%. Nausea occurs in 3.2% of the patients.

Localized pain, vomiting, paresthesia, dizziness and localized warmth occur in less than 2% of the patients.

The following additional adverse events occur in less than 1% of the patients:

Body as a Whole: Injection site symptoms, namely, pain, warmth, burning; localized burning sensation, substernal chest pain, fever, weakness, generalized coldness, localized edema, tiredness, chest tightness, regional lymphangitis, anaphylactoid reactions (characterized by cardiovascular, respiratory and cutaneous symptoms).

Cardiovascular: Hypotension, vasodilation, pallor, non-specific ECG changes, angina pectoris, phlebitis.

Digestive: Gastrointestinal distress, stomach pain, teeth pain, increased salivation.

Nervous System: Agitation, thirst, convulsions (including grand mal).

Respiratory System: Throat irritation, rhinorrhea, sneezing, dyspnea, wheezing, laryngismus, cough.

Skin: Rash, sweating, pruritus, urticaria (hives).

Special Senses: Tinnitus, conjunctivitis, visual field defect, taste abnormality, dry mouth, lacrimation disorder (tearing), eye irritation.

Laboratory: Transient elevation of serum transaminases.

The following other adverse events were reported. A causal relationship has neither been established nor refuted.

Body as a Whole: Back pain, pain, generalized warmth.

Cardiovascular: Hypertension, tachycardia, migraine, syncope, death related to myocardial infarction or other undetermined causes.

Digestive: Constipation, diarrhea.

Nervous System: Anxiety, anorexia, nystagmus, drowsiness, diplopia, stupor.

Skin: Facial edema, erythema multiforme, epidermal necrolysis.

Special Senses: Eye pain, ear pain.

Data from foreign studies did not reveal any additional adverse experiences.

OVERDOSAGE

The LD_{50} of intravenously administered gadopentetate dimeglumine injection in mice is 5-12.5 mmol/kg and in rats it is 10-15 mmol/kg. The LD_{50} of intravenously administered MAGNEVIST® Injection in dogs is greater than 6 mmol/kg.

Clinical consequences of overdose with MAGNEVIST® Injection have not been reported.

DOSAGE AND ADMINISTRATION

The recommended dosage of MAGNEVIST® Injection is 0.2 mL/kg (0.1 mmol/kg), administered intravenously, at a rate not to exceed 10 mL per minute. More rapid injection rates may be associated with nausea. The maximum total dose is 20 mL. Any unused portion must be discarded.

DOSAGE CHART

Body Weight (kg)	Dose in mL	Approx Duration of Injection in Seconds
10	2.0	20
20	4.0	30
30	6.0	40
40	8.0	50
50	10.0	60
60	12.0	70
70	14.0	80
80	16.0	95
90	18.0	110
100	20.0	120

To ensure complete injection of the contrast medium, the injection should be followed by a 5-mL normal saline flush. The imaging procedure should be completed within 1 hour of injection of MAGNEVIST® Injection.

Parenteral products should be inspected visually for particulate matter and discoloration prior to administration, whenever solution and container permit.

For full prescribing information, see package insert.

Caution: Federal Law Prohibits Dispensing Without Prescription.

Treatment of Multiple Sclerosis With Hyperbaric Oxygen

Results of a National Registry

Eric P. Kindwall, MD; Michael P. McQuillen, MD; Bhupendra O. Khatri, MD;
Harvey W. Gruchow, PhD; Marilyn L. Kindwall, MS

• Three hundred twelve patients were entered into a long-term study of effects of hyperbaric oxygen on multiple sclerosis. The protocol called for an initial 20 treatments in either the monoplace or multiplace chamber on a daily basis followed by monthly booster treatments for 2 years. One hundred seventy neurologists and 22 institutions provided data for this study. There was no control group, but the study was based on Schumacher's postulation that a scientifically valid study to test the efficacy of a new therapy was possible by choosing patients who were definitively diagnosed with multiple sclerosis and following them up for 2 years after the imposed treatment. If the overwhelming majority of the subjects failed to get worse over the 2-year observation period, the efficacy of the treatment would be manifest. The expanded Kurtzke Disability Status Scale (EDSS) was used to assess the severity of the disease state. The dropout rate was high with only 76% (237 of 312 patients) finishing the initial 20 treatments. Twenty-two percent (69 of 312) finished 1 year of booster therapy, and 9% (28 of 312) completed 2 years of monthly boosters. The mean deterioration on the Kurtzke EDSS score was 0.93 or almost a full step from the beginning of treatment until the last evaluation. There was no difference in outcome between those who had the shortest and longest periods of time between onset of symptoms and hyperbaric oxygen treatment. Treatment pressure made no difference in outcome. Changes in the Kurtzke EDSS score bore no relationship to the use of booster treatment. Patients who were reasonably well off at the onset of treatment with initial Kurtzke EDSS scores of 1 or 2 ($n = 21$) deteriorated by an average of 1.7 Kurtzke points. Those patients whose initial Kurtzke EDSS scores were greater than 2 ($n = 164$) deteriorated on an average of 0.82 points. Of interest was that 19.5% (39 of 200) of the patients reported a temporary improvement in bladder function, but improvement was maintained in only 11 patients (5.5%) at 2-year follow-up. Fifteen patients (7.5%) indicated long-term worsening. There was no significant change in the working status of the patients following hyperbaric oxygen treatment. Although this study treated the patients in accordance with protocols reported to produce a benefit in multiple sclerosis, we were unable to substantiate any useful long-term effect of hyperbaric oxygen therapy.

(*Arch Neurol.* 1991;48:195-199)

Starting in 1978, anecdotal reports that multiple sclerosis benefited from treatment with hyperbaric oxygen (HBO) heightened interest in this form of treatment among patients and neurologists alike. Treated cases were reported from the United States, Italy, Czechoslovakia, the United Kingdom, Sweden, and Brazil.[1-4]

Although the mechanism for improvement with HBO treatment was not known, HBO has been shown by Prokop and Grasso[5] to ameliorate experimental allergic encephalomyelitis in guinea pigs. Both survival and delay in time of onset was increased in the treated animals. Warren et al[6] independently confirmed that development of encephalomyelitis in guinea pigs and rats was delayed by up to 34 days after injection of antigen when animals immediately began treatment with HBO at 2 atmospheres absolute (ATA).

In 1983, the *New England Journal of Medicine* published the study by Fischer et al,[7] in which 40 patients with advanced chronic multiple sclerosis were randomly divided into an HBO treatment group and a group that received a 10% oxygen mixture. Both groups were treated at a pressure of 2 ATA for 90 minutes once daily for a total of 20 exposures. "Objective improvement" (defined as change in the Kurtzke Disability Status Scale, a functional-system scale, and a fatigability scale) occurred in 12 of 17 patients treated with HBO and in only one of 20 patients treated under normoxic conditions ($P < .0001$). Even though improvement was short-lived in seven of the treated patients, it was long lasting in five. At the 1-year follow-up, deterioration was noticed in two patients in the HBO group and in 11 of the patients in the normoxic group ($P < .0008$).

Because patients began to flock to HBO centers for treatment after the appearance of the article by Fischer et al, it was imperative that a study be devised to gather meaningful data from the treatment results of these patients. Schumacher[8] postulated that a scientifically adequate pilot study was possible without the use of a control group by choosing patients who were pursuing a downhill course, or those who had experienced serious exacerbations, with following up the patients for 2 years after the imposed treatment. If 90% to 100% of such patients failed to get worse, the efficacy of the treatment would be manifest. It was clear that data obtained from a long-term uncontrolled study would be crude compared with those derived from strictly controlled double-blind studies. Therefore, a more rigorous

Table 1.—Kurtzke Expanded Disability Status Scale Scores

Score	Description
0.0	Normal
1.0	No disability, minimal signs, eg, vibratory decrease, Babinski's sign
2.0	Minimal disability, eg, slight gait, sensory, visuomotor disturbances
3.0	Moderate disability, although fully ambulatory, eg, monoparesis, moderate ataxia, or combination of lesser dysfunction
4.0	Relatively severe disability, although fully ambulatory and able to be self-sufficient and up and about for some 12 h a day Able to walk without aid or rest about 500 m (5 blocks)
4.5	Able to walk without aid or rest about 300 m (3 blocks)
5.0	Disability severe enough to preclude ability to work a full day without special provisions Able to walk without aid or rest about 200 m
5.5	Able to walk without aid or rest about 100 m
6.0	Constant assistance (unilateral, cane, crutch, brace) is required to walk about 20 m without resting
6.5	Constant assistance (bilateral, walker, canes, crutches) is required to walk about 20 m without resting
7.0	Unable to walk beyond 5 m (even with aid); essentially restricted to wheelchair (some 12 h a day); wheels self; transfers alone
7.5	Unable to take a few steps; restricted to wheelchair; needs help in transfer; can operate motorized wheelchair only
8.0	Essentially restricted to bed, but may be out of bed itself much of the day; retains many self-care functions; effective use of arms
8.5	Restricted to bed much of the day; some effective use of arms; retains some self-care functions
9.0	Helpless bed patient; can communicate and eat
9.5	Totally helpless; unable to communicate effectively
10.0	Death due to multiple sclerosis

definition of *benefit* had to be applied to achieve some validity. In order to meet Schumacher's criteria for evidence of therapeutic benefit, favorable results would rest on prevention of exacerbation or of further progression of the disease in an overwhelming majority of subjects over a 2-year period of observation. Using a format based on Schumacher's criteria, we created a registry of HBO-treated patients and embarked on a 3-year prospective study of the effects of HBO in the treatment of multiple sclerosis. The study commenced in February 1983 and ended in January 1987. A total of 22 institutions with hyperbaric treatment facilities contributed the data on which this study is based.

PATIENTS AND METHODS

Registry Membership

Participation in this study was restricted to only those centers that could meet all of the registry protocol eligibility criteria as outlined below. The Registry protocol required that:

1. Only those institutions having an Institutional Review Board designed and functioning under the National Institutes of Health, Bethesda, Md, guidelines could participate in the Registry.
2. The protocol be approved by each participating hospital's Institutional Review board.
3. No professional charges were to be made to the patient. Hyperbaric chamber charges could be charged to the patient but were to be out-of-pocket costs only, presuming it was possible to break this figure out of total operational costs. Provisionally, some insurance companies paid for treatment out of enlightened self-interest.
4. Each patient had to agree to remain in the Registry at least 2 years barring unforeseen circumstances.
5. Patients could only enter the protocol through referral by their neurologists. All neurologic evaluations had to be carried out by Board eligible or Board certified neurologists. All patients with multiple sclerosis treated with HBO at a participating institution had to be entered into the Registry. All patients had to sign an informed consent before entering the Registry.

The Registry data were maintained by the Biostatistical Department at the Medical College of Wisconsin in Milwaukee.

Patient Selection

Only those patients with clinically definite multiple sclerosis and with no contraindications to HBO therapy were allowed to participate in the study. There were no age limitations.

HBO Treatment Protocols

The protocol called for 20 initial treatments on a once-daily basis at least 5 days each week, followed by monthly booster treatments for 2 years. Other than to set limits for reasons of oxygen toxicity, the protocol did not stipulate the HBO treatment pressures rigidly. This was by intent as there had been no study published that had conclusively established an optimal protocol. No facility was permitted to administer oxygen at a pressure greater than 3 ATA and at that pressure for no longer than 90 minutes. In the available literature, treatment pressure has ranged between 1.5 and 3 ATA and treatment has been carried out in both multiplace and monoplace chambers. Institutions were urged to use one of the protocols that had already appeared in the literature as reporting to produce "benefit" as it was felt that only in this way could it be determined which method could prove or disprove the long-term usefulness of existing protocols.

Clinical Evaluation

The severity of the patient's disability was graded using the expanded Kurtzke Disability Status Scale (EDSS) as shown in Table 1. All patients were examined at entry, after 20 HBO treatments, and at 6, 12, 18, and 24 months while they received monthly booster HBO. Standardized evaluation and eligibility forms were sent to all participating institutions.

Chamber Equipment

Patients in this study were treated in either multiplace or monoplace chambers. In the multiplace chambers, masks were generally of the tight-fitting double-seal oronasal aviator type or the patient used a tightly sealed Duke head tent with adequate oxygen flow. At 2 ATA with a perfect mask fit, a Pa_{O_2} should approach 1200 mm Hg. In a monoplace chamber, this is not a problem as the patient's FI_{O_2} is guaranteed to be 100% as the chamber is pressurized with pure oxygen.

Concomitant Management of Patients

Patients were continued on whatever therapeutic regimen they had been receiving prior to entry into the study, including physical therapy. Because of a tendency for corticotropin or corticosteroids to aggravate oxygen toxicity, it was urged that such medications be tapered and stopped prior to beginning HBO treatment. The same applied to baclofen, which is an analogue of γ-aminobutyric acid. The HBO is known to disrupt γ-aminobutyric acid metabolism. Prednisone had been used by 196 (51.2%) of patients at some time; 103 (26.9%) had taken corticotropin. Only three (0.8%) of the patients continued to take steroids during the study. One patient continued with unspecified immunotherapy during HBO treatment.

Complications

No seizures were reported. Thirty-nine patients (10.2%) mentioned "complications" after the first 20 treatments; over 90% of these involved simple ear or sinus discomfort. Occasional nausea was recorded. No cases of blindness were reported.

Statistical Analysis

Standard statistical methods were used for analysis. The independence of frequency distributions was tested with the χ^2 statistic. Mean values were compared between groups using the two-sample t test and an analysis of variance. Associations between two continuous variables were assessed by the Pearson correlation coefficient. Analyses were carried out using the Statistical Program for Social Science software, release 3.0 for the Micro VAX II Computer (Digital Equipment Co, Maynard, Mass).[9]

Table 2.—Clinical Outcome Following Hyperbaric Oxygen Treatment

	Mean Kurtzke EDSS Score (SD)*			
	At Entry	After 20 HBO Treatments	2-y Follow-up	Deterioration
All patients	5.5 (2.0) (n = 312)	5.4 (2.1) (n = 239)	6.4 (2.0)	+0.93 (1.44)†
Patients with follow-up	5.5 (2.1) (n = 185)	5.5 (2.1) (n = 146)	6.4 (2.0) (n = 200)	+0.93 (1.44)† (n = 185)

*EDSS indicates expanded Disability State Scale; HBO, hyperbaric oxygen.
†$P = .01$

Table 3.—Results According to Disease Type*

	Mean Kurtzke EDSS Score (SD)			
Type of Multiple Sclerosis	At Entry	After 20 HBO Treatments	2-y Follow-up	Deterioration
Chronic stable (n = 41)	5.4 (2.2)	5.0 (2.4)	5.9 (2.4)	+0.5 (1.2) (n = 38)
Chronic progressive (n = 156)	5.9 (1.8)	5.9 (1.9)	6.9 (1.7)	+1.0 (1.4)† (n = 24)
Relapsing remitting (n = 23)	3.5 (1.8)	3.4 (2.0)	4.7 (2.1)	+1.3 (2.0) (n = 22)

*EDSS indicates expanded Disability State Scale; HBO, hyperbaric oxygen.
†$P < .01$; for all other differences, P is not significant.

RESULTS

Three hundred eighty-three patients were logged into the study; initial complete data were received on 317 patients, of whom 312 (81.4%) actually received the treatment. All the patients included in the study had enough criteria to confer a definite diagnosis of multiple sclerosis. Thirty-five percent of the patients were male and 65% were female. The mean age at entrance to the study was 43.7 years (range, 18 to 70 years). The mean age at diagnosis was 35 years (range, 12 to 59 years); mean age at onset of symptoms was 32 years (range, 10 to 59 years); and median age at onset of symptoms was 31 years, while the median age for diagnosis was 34 years.

Each patient was referred by a neurologist with the evaluation form being completed by the same physician. There were a total of 170 neurologists who referred patients to the study and who performed evaluations. As with any large study that involved multiple physicians over a period of years, complete information was not received on all patients as the neurologists sometimes left portions of the questionnaire uncompleted or, in some instances, information was not available. For this reason, the number of patients will be found to vary in the analyses. For those 239 patients on whom pressure data for the initial series of treatments were available, 13.6% were treated exclusively at 1.5 ATA, 19.6% were treated at pressures varying between 1.5 and 2 ATA, 58% were treated at 2 ATA, and 7.7% were treated at 2.4 ATA. One hundred ninety-seven patients (51.3%) were treated in multiplace chambers and 139 (44.5%) in monoplace units. For 13 patients (4.2%), this information was not provided. Of the 312 patients who began HBO therapy, 209 (67%) were diagnosed as chronic progressive, 39 patients (12.5%) were chronic stable and 64 patients (20.5%) carried relapsing remitting diagnosis. Two hundred eighty-three patients (90.7%) underwent at least one of the initial 20 HBO treatments; 120 patients (38.5%) finished 6 months of booster treatments; 69 patients (22.1%) finished 12 months, and 37 patients (11.9%) finished 18 months of booster treatments. The number of patients who completed a full 2 years of monthly booster treatments was 28 (9%). Because of a large number of dropouts, the loss of interest on the part of both patients and neurologists, it was not possible to carry out all evaluations as scheduled. Therefore, at the end of the study, it was necessary to contact 200 of the patients by telephone to gather data on final outcome. The purpose of this telephone survey was to fill in gaps in the data, and to determine the patient's final Kurtzke EDSS score by self-assessment and his/her life status. (The overall agreement between patient's self-assessment and the neurologist's score on the Kurtzke scale is 0.93, according to Scheinberg et al.[10])

Table 2 shows the mean Kurtzke EDSS scores at entry, after 20 HBO treatments, and at 2-year follow-up. In the 185 patients for whom both initial and final Kurtzke EDSS scores were obtained by the evaluating neurologist, the mean deterioration in the Kurtzke EDSS score was 0.93 or almost a full step from the beginning of treatment until the last evaluation, 2 years later. Follow-up data on the rest of the patients was obtained by calling them and assigning a Kurtzke EDSS score based on their description of their condition. There was no significant difference in outcome between those who had the shortest period of time between onset of symptoms and initiation of HBO and those who had the longest time between those two historical points ($P = .9599$).

Table 4.—The Role of Booster Therapy

	Mean Kurtzke EDSS Score (SD)*		
Patients	At Entry	2-y Follow-up	Deterioration
Receiving boosters	5.3 (2.1) (n = 192)	6.1 (2.1) (n = 110)	+0.93 (1.5)† (n = 102)
Not receiving boosters	5.7 (1.9) (n = 170)	6.8 (1.9) (n = 90)	+0.93 (1.4)† (n = 83)

*EDSS indicates expanded Disability State Scale.
†P not significant.

Table 3 summarizes the effect of HBO therapy on patients with different forms of multiple sclerosis. Deterioration in the mean Kurtzke EDSS score occurred in all these groups; however, this was significant ($P < .01$) only in the chronic progressive group of patients. As shown in Table 4, it was of no clinical significance whether the patients did or did not receive booster treatments after the completion of initial HBO therapy. At 6 months, changes in EDSS scores were unrelated to the number of boosters ($P = .29$). Of 28 patients who completed 2 years of booster treatments, one had less than once-a-month treatment and three had more than monthly treatments (the maximum being 61 treatments in one patient). The different pressures at which treatments were rendered—either during the initial course (Table 5) or during the booster phase (Table 6)—did not influence the course of disease progression.

Visual Changes

One hundred sixty (80%) of the 200 patients reported no change in vision; 15 (7.5%) experienced temporary im-

Table 5.—Significance of Treatment Pressure in the Initial Course*

	Kurtzke EDSS Score (SD)		
	Initial	Final	Initial to Final Change in Score
Initial treatment pressure			
≤1.75 ATA	5.6 (2.0) (n = 42)	6.9 (2.0) (n = 29)	+0.80 (1.55)† (n = 27)
>1.75 ATA	5.5 (2.0) (n = 112)	6.6 (1.9) (n = 72)	+1.24 (1.34)† (n = 64)

*EDSS indicates expanded Disability State Scale; ATA, atmospheres absolute.
†$P = .17$.

Table 6.—Significance of Booster Treatment Pressure*

	Kurtzke EDSS Score (SD)		
	Initial	Final	Initial to Final Change in Score
Booster treatment pressure			
≤1.75 ATA	5.3 (1.7) (n = 24)	6.2 (1.9) (n = 26)	+0.88† (1.5) (n = 24)
Mixed	4.8 (2.4) (n = 8)	5.9 (2.1) (n = 8)	+0.63† (1.5) (n = 8)
≥2 ATA	5.1 (2.2) (n = 68)	6.2 (2.1) (n = 79)	+1.03† (1.5) (n = 68)

*EDSS indicates expanded Disability State Scale; ATA, atmospheres absolute.
†$P = .73$ (not significant).

provement; 10 (5%) reported lasting improvement; and 15 (7.5%) experienced permanent worsening of vision, following HBO therapy. The HBO itself can cause temporary worsening of myopia and temporary improvement in presbyopia. Usually, these changes spontaneously reverse themselves after 6 weeks. Visual changes are normally seen only after 20 or more closely spaced treatments, typically in patients older than 40 years of age. No cases of blindness or exacerbation of optic neuritis associated with HBO were reported. The authors are aware of one case of complete and permanent blindness with HBO treatment of multiple sclerosis that occurred at another institution prior to the beginning of this study.

Bowel Function

When queried about bowel function, 162 (81%) of 200 patients reported no change, 22 patients (11%) reported temporary improvement, and 5 patients (2.5%) reported lasting improvement. Eleven (5.5%) patients reported a worsening of bowel function that persisted after HBO treatment had been completed.

Bladder Function

Of particular interest were the reports of change in bladder function. Thirty-nine (19.5%) of 200 patients reported temporary improvement in bladder functions; 11 (5.5%) were improved at 2-year follow-up; 15 (7.5%) experienced worsening; and 135 (67.5%) patients reported no change. Changes in bladder function were independent of the changes in Kurtzke EDSS scores.

Working Status

Working was defined as holding a salaried/remunerated job or carrying out of normal housekeeping duties if the patient elected to remain in the home. Forty-four (63.8%) of 69 men and 120 (92%) of 130 women were not working at the start of the study. No significant change was noted in the working status of these patients following HBO treatment.

Improvement Related to Severity

Patients who were reasonably well off at the onset of treatment (initial Kurtzke EDSS scores, 1 or 2; n = 21) deteriorated by an average of 1.7 Kurtzke points, whereas patients whose initial Kurtzke EDSS scores were greater than 2 (n = 164) deteriorated an average of 0.82 points ($P = .03$). Thus, the worse a patient's condition was at the start of HBO, the less the deterioration noted.

COMMENT

There is no benefit from HBO in multiple sclerosis manifest in this study. There is always a possibility that in uncontrolled short-term studies a placebo effect may be apparent. This may have been true in our case as after the initial 20 treatments, there seemed to be a trend toward improvement. However, in other short-term double-blind controlled studies carried out since the publication of the report by Fischer et al,[7] no significant differences were found between the treated patients and the control subjects.[11-17] The placebo response is of great importance when dealing with any therapeutic trial in multiple sclerosis. While the most definitive answer in a clinically variable disorder such as multiple sclerosis can only be obtained through a double-blind controlled therapeutic trial of sufficient duration and with enough patients, the results of this study confirm the negative results of short-term double-blind randomized control studies.

Pallotta et al[4] reported on "good results" in the treatment of six patients. Boschetty and Cernoch[1] reported that the use of HBO in multiple sclerosis led to a "remission of symptoms." Formai et al[2] found that in all their cases the disease was worsening as therapy commenced, but "the changes occurred almost exclusively toward an improvement after several months of observation." They also stated that "the changes associated with or following oxy-hyperbaric treatment could not be confused with those due to clinical fluctuations of the basic illness." Neubauer[3] described the treatment of 250 patients with multiple sclerosis reporting "dramatic" improvement in 39% of the cases and minimal to moderate improvement in 52%. The remainder (9%) showed no change. "Dramatic" improvement was defined as "complete or near total remission." He felt that the best results were seen in patients ill less than 5 years.

Neubauer[3] has stated that pressures in excess of 2 ATA may prove too toxic and may produce further damage to the central nervous system. Yet, Pallotta et al[4] had used 3 ATA and reported good results. Neubauer had initially recommended once- or twice-a-day treatment at 1.5 ATA for 60 to 90 minutes "as tolerated" for the first four treatments, and then 2 ATA for 16 more treatments lasting 60 to 90 minutes "as tolerated" or depending on "clinical response." It was using this protocol that he reported his good results in the treatment of 250 patients. None of the investigators in our study reported any change in "clinical response" during the course of therapy that they could use as an indication for change in treatment pressure, nor were any patients reported "intolerant" to 2 ATA who had "tolerated" 1.5 ATA. Neubauer gave no explanation for the rationale for starting at 1.5 ATA and then going to 2 ATA other than "clinical response."

Using his experience, Neubauer further stated that long-term HBO follow-up is beneficial and that one treatment monthly at 2 ATA was usually sufficient. He also stated that when long-term HBO follow-up is offered, intervals between treatments could be lengthened as much as 3 months. As clinical experience by 1983 had indicated that benefits of HBO treatment might be temporary, booster treatments were included in the protocol at monthly intervals.

Multiple sclerosis is an extraordinarily difficult disease in which to assess the efficacy of any given therapy. Some series[18-20] have reported the placebo response to range from 30% to 80%. Additionally, the disease is often characterized by exacerbations or remissions that can extend over a period of years. For these reasons, control subjects are required in the usual study to document small differences that may be seen in patients treated with any new modality.

It was using the multiplace chamber even with the attendant problem of mask leaks that Fischer reported his good results. Fischer had the impression that those patients whose PaO_2 was at least 1000 mm Hg during treatment did better than did those whose arterial PaO_2 did not reach that level. In the monoplace chamber, high arterial levels of oxygen are guaranteed as the chamber atmosphere is 100% oxygen. We were unable to show differences in outcome, however, referable to the partial PO_2.

There are many who still feel that HBO is a useful modality in the treatment of multiple sclerosis and cite largely uncontrolled statistics to prove their point. Additionally, they now contend that boosters should be given at weekly intervals instead of monthly if results are to be seen. This is despite the fact that *the early highly encouraging reports were based on monthly booster therapy,* and not weekly therapy. We made a good-faith effort to apply HBO treatment in the clinical setting as advocated by its proponents, but it is obvious that from the high number of dropouts and general loss of interest in this modality the patients themselves were not able to recognize the benefits.

It is possible that repeated HBO treatment can provide amelioration on a temporary basis for some symptoms (bladder function, for example), but the cumbersome and expensive nature of this treatment precludes frequent treatment in the usual case. We only required monthly boosters for the purpose of our study, but the majority of the patients could not even comply with that requirement. Thus, it is apparent that, as a mass treatment, HBO therapy has shown itself to be impractical in the US. If we or any of the other centers that conducted short-term, carefully controlled double-blind studies had been able to demonstrate a conclusive benefit for this form of treatment, there would be a good rationale for attempting to construct low-technology monoplace units that could be mass produced and manned by volunteers from the multiple sclerosis community. However, at least in our hands, and based on reports of the double-blind control studies carried out in the United States and the United Kingdom, and elsewhere, this has not been shown to be the case.

This study was supported, in part, by a grant from the National Multiple Sclerosis Society, New York, NY.

This study would not have been possible without the help of the following participating institutions: Bronson Methodist Hospital, Kalamazoo, Mich; Brookside Hospital, San Pablo, Calif; Butterworth Hospital, Grand Rapids, Mich; Carraway Methodist Medical Center, Birmingham, Ala; Central Texas Hyperbaric Center, Austin; Edgewater Hospital, Chicago, Ill; Jewish Hospital, Louisville, Ky; Kaiser Foundation Hospital, Honolulu, Hawaii; Kauai Veterans Memorial Hospital, Waimea, Hawaii; Lorain Community Hospital, Lorain, Ohio; McKellar Hospital, Thunder Bay, Ontario; Memorial Medical Center, Corpus Christi, Tex; Mercy Hospital, San Diego, Calif; Mercy Hospital, Scranton, Pa; Northside Hospital, Johnson City, Tenn; Peralta Hospital, Oakland, Calif; Public General Hospital, Chatham, Ontario; Reed Neurological Center, Los Angeles, Calif; Rocky Mountain Multiple Sclerosis Center, Inglewood, Colo; St Francis Hospital, Colorado Springs, Colo; St Luke's Hospital, St Louis, Mo; St Luke's Hospital, Milwaukee, Wis; Sutter General Hospital, Sacramento, Calif; Swedish Hospital Medical Center, Seattle, Wash; Tobermory (Ontario) Hyperbaric Facility; University Hospital, London, Ontario; Valley Hospital Medical Center, Van Nuys, Calif.

SANDOZPHARMACEUTICALS
Corporation, E. Hanover, NJ 07936 (201) 503-7500

C-CAF-0689-01
© 1991 Sandoz Pharmaceuticals Corporation

Cafergot®

(ergotamine tartrate and caffeine) tablets, USP
(ergotamine tartrate and caffeine) suppositories, USP

DESCRIPTION

Cafergot® (ergotamine tartrate and caffeine) Tablet

ergotamine tartrate USP	1 mg
caffeine USP	100 mg

Inactive Ingredients: acacia, carnauba wax, lactose, methylparaben, povidone, propylparaben, sodium benzoate, sorbitol, starch, stearic acid, sucrose, synthetic black ferric oxide, synthetic red ferric oxide, synthetic yellow ferric oxide, talc, tartaric acid, and titanium dioxide.

Cafergot® (ergotamine tartrate and caffeine) Suppository

ergotamine tartrate USP	2 mg
caffeine USP	100 mg

Inactive Ingredients: cocoa butter NF and tartaric acid NF.

Cafergot® (ergotamine tartrate and caffeine) suppositories are *sealed* in foil to afford protection from cocoa butter leakage. If an unavoidable period of exposure to heat softens the suppository, it should be chilled in ice-cold water to solidify it before removing the foil.

ACTIONS: Ergotamine is an alpha adrenergic blocking agent with a direct stimulating effect on the smooth muscle of peripheral and cranial blood vessels and produces depression of central vasomotor centers. The compound also has the properties of serotonin antagonism. In comparison to hydrogenated ergotamine, the adrenergic blocking actions are less pronounced and vasoconstrictive actions are greater.

Caffeine, also a cranial vasoconstrictor, is added to further enhance the vasoconstrictive effect without the necessity of increasing ergotamine dosage.

Many migraine patients experience excessive nausea and vomiting during attacks, making it impossible for them to retain any oral medication. In such cases, therefore, the only practical means of medication is through the rectal route where medication may reach the cranial vessels directly, evading the splanchnic vasculature and the liver.

INDICATIONS

Cafergot® (ergotamine tartrate and caffeine)

Indicated as therapy to abort or prevent vascular headache, e.g., migraine, migraine variants or so-called "histaminic cephalalgia".

CONTRAINDICATIONS: Peripheral vascular disease, coronary heart disease, hypertension, impaired hepatic or renal function, sepsis and pregnancy.

Hypersensitivity to any of the components.

PRECAUTIONS: Although signs and symptoms of ergotism rarely develop even after long term intermittent use of the orally or rectally administered drugs, care should be exercised to remain within the limits of recommended dosage.

Ergotism is manifested by intense arterial vasoconstriction, producing signs and symptoms of peripheral vascular ischemia. Ergotamine induces vasoconstriction by a direct action on vascular smooth muscle. In chronic intoxication with ergot derivatives, headache, intermittent claudication, muscle pains, numbness, coldness and pallor of the digits may occur. If the condition is allowed to progress untreated, gangrene can result.

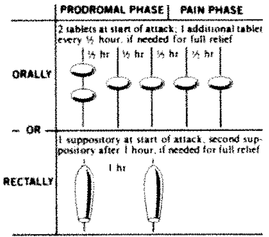
While most cases of ergotism associated with ergotamine treatment result from frank overdosage, some cases have involved apparent hypersensitivity. There are few reports of ergotism among patients taking doses within the recommended limits or for brief periods of time. In rare instances, patients, particularly those who have used the medication indiscriminately over long periods of time, may display withdrawal symptoms consisting of rebound headache upon discontinuation of the drug.

There have been reports of drug abuse and psychological dependence in patients on Cafergot® (ergotamine tartrate and caffeine) therapy. Due to the chronicity of vascular headaches, it is imperative that patients be advised not to exceed recommended dosages with long-term use to avoid ergotism.

ADVERSE REACTIONS: Vasoconstrictive complications, at times of a serious nature, may occur. These include pulselessness, weakness, muscle pains and paresthesias of the extremities and precordial distress and pain. Although these effects occur most commonly with long-term therapy at relatively high doses, they have also been reported with short-term or normal doses. Other adverse effects include transient tachycardia or bradycardia, nausea, vomiting, localized edema and itching.

DOSAGE AND ADMINISTRATION

Procedure: For the best results, dosage should start at the first sign of an attack.



PRODROMAL PHASE
PAIN PHASE
2 tablets at start of attack; 1 additional tablet every ½ hour, if needed for full relief
½ hr
½ hr
½ hr
½ hr
ORALLY
— OR —
1 suppository at start of attack, second suppository after 1 hour, if needed for full relief
1 hr
RECTALLY

Early Administration Gives Maximum Effectiveness

MAXIMUM ADULT DOSAGE

Orally: Total dose for any one attack should not exceed 6 tablets.

Rectally: Two suppositories is the maximum dose for an individual attack.

Total weekly dosage should not exceed 10 tablets or 5 suppositories.

In carefully selected patients, with due consideration of maximum dosage recommendations, administration of the drug at bedtime may be an appropriate short-term preventive measure.

OVERDOSAGE: The toxic effects of an acute overdosage of Cafergot® (ergotamine tartrate and caffeine) are due primarily to the ergotamine component. The amount of caffeine is such that its toxic effects will be overshadowed by those of ergotamine. Symptoms include vomiting, numbness, tingling, pain and cyanosis of the extremities associated with diminished or absent peripheral pulses; hypertension or hypotension; drowsiness, stupor, coma, convulsions and shock. A case has been reported of reversible bilateral papillitis with ring scotomata in a patient who received five times the recommended daily adult dose over a period of 14 days.

Treatment consists of removal of the offending drug by induction of emesis, gastric lavage, and catharsis. Maintenance of adequate pulmonary ventilation, correction of hypotension, and control of convulsions are important considerations. Treatment of peripheral vasospasm should consist of warmth, but not heat, and protection of the ischemic limbs. Vasodilators may be used with benefit but caution must be exercised to avoid aggravating an already existent hypotension.

HOW SUPPLIED

Cafergot® (ergotamine tartrate and caffeine) Tablets

Shell pink colored, sugar coated, imprinted "CAFERGOT" on one side, "S" on other side. Bottles of 250, NDC 0078-0034-28, and cartons of three SigPak® (dispensing unit) packages, each containing 30 tablets in individual blisters, NDC 0078-0034-42.

Cafergot® (ergotamine tartrate and caffeine) Suppositories

Sealed in fuchsia-colored aluminum foil, imprinted "S CAFERGOT® SUPPOSITORY 78-33 SANDOZ". Boxes of 12, NDC 0078-0033-02.

[DECEMBER 1, 1990 CAF-Z26]

Alterations in Brain Phosphate Metabolite Concentrations in Patients With Human Immunodeficiency Virus Infection

Raymond F. Deicken, MD; Bruno Hubesch, PhD; Peter C. Jensen, MD; Dominique Sappey-Marinier, PhD; Pamela Krell, PhD;
Amy Wisniewski, PhD; Douglas Vanderburg, MD; Reginald Parks, MPH; George Fein, PhD; Michael W. Weiner, MD

• Human immunodeficiency virus (HIV)–infected individuals often demonstrate neuropsychiatric impairment; however, it is unclear how brain metabolism may be altered in such patients. We used in vivo phosphorus 31 magnetic resonance spectroscopy to noninvasively assess brain energy and phospholipid metabolism by measuring brain concentrations of adenosine triphosphate (ATP), phosphocreatine (PCr), and inorganic phosphate (Pi), as well as phospholipid compounds and intracellular pH. In study 1, 17 HIV-seropositive men with varying degrees of neuropsychiatric impairment and six control subjects were studied. Localized spectra were obtained from a heterogeneous 5 × 5 × 5-cm volume of interest (VOI). Patients with HIV infection had a significantly lower ATP/Pi ratio and a trend for a lower PCr/Pi ratio than did the control group. In addition, the ATP/Pi and PCr/Pi ratios were both significantly negatively correlated with overall severity of neuropsychiatric impairment. In study 2, three HIV-seropositive men with neuropsychiatric impairment were compared with 11 HIV-seronegative men. Localized phosphorus 31 magnetic resonance spectra were obtained from two relatively homogeneous VOIs: (1) a predominantly white matter VOI, and (2) a predominantly subcortical gray matter VOI. The three HIV-infected patients demonstrated significantly decreased ATP and PCr concentrations in the white matter VOI. These results suggest that HIV infection of the brain may impair brain cellular oxidative metabolism and that the degree of metabolic compromise may be related to the severity of neuropsychiatric impairment.

(*Arch Neurol.* 1991;48:203-209)

Compelling evidence exists that direct central nervous system (CNS) infection by the human immunodeficiency virus (HIV) occurs in a large proportion of HIV-infected individuals and often results in a neurological syndrome, acquired immunodeficiency syndrome (AIDS) dementia complex (ADC). This complex is characterized by disordered cognition, motor function, and behavior.[1-4] About 75% of autopsies on randomly selected patients with AIDS show CNS pathology,[5] although only about 40% of patients are neurologically symptomatic.[6] Neurologic complications of AIDS may result from diffuse encephalopathy secondary to direct HIV infection of the CNS or from opportunistic CNS infections secondary to the immunosuppressive effects of HIV.[7] Of 30 autopsied adult patients with AIDS,[2] 80% had neurological signs or symptoms and 60% had histopathologic findings of subacute encephalitis; preliminary data using monoclonal antibodies against the p24 antigen in frozen brain tissue showed HIV in the CNS, especially in multinucleated cells. In over 90% of 70 autopsied patients,[1] abnormalities were predominantly located in the white matter and subcortical areas, with relative sparing of the cortex; progressive dementia was present in 46 patients. Human immunodeficiency virus has been detected in the white matter and basal ganglia of eight demented patients[8] and in the cerebral spinal fluid or neural tissue of 11 of 13 patients with AIDS, where subacute encephalopathy, including monocyte/macrophage infiltration, was found.[9] Subacute encephalitis consistent with a viral infection of the CNS was histologically defined in 12 patients with AIDS in whom the white matter was more severely affected than was the gray matter. In most cases, the HIV infection was restricted to capillary endothelial cells, mononuclear cells, and giant cells.[10] In the brains of two patients, it was possible to identify mononucleated and multinucleated macrophages that supported replication of the AIDS retrovirus in brain tissue.[11] In children with AIDS, study of CSF has shown HIV antigen indicating viral expression in the CNS, correlated with the occurrence of progressive encephalopathy.[12] On the basis of culturing HIV from the cerebrospinal fluid, it was concluded that HIV is neurotropic, capable of causing acute meningitis, and responsible for

AIDS-related chronic meningitis and dementia.[13]

Results of neuroimaging studies have consistently indicated preferential subcortical involvement in HIV infection. Subcortical structures have been shown to be affected to a greater degree than have the cortical structures on positron emission tomographic studies, at least in the initial phases of the syndrome.[14] Magnetic resonance imaging (MRI) of patients with AIDS and patients with the AIDS-related complex (ARC) reveals multiple small and discrete lesions of high signal intensity in subcortical white matter, as well as ventricular and sulcal enlargement that is suggestive of brain atrophy.[15,16]

Navia and colleagues[1] suggested that impaired memory, concentration difficulties, and psychomotor slowing represent the most common early manifestations of ADC. This presentation is similar to that seen in other diseases with primary damage to white matter and subcortical structures.[17] It is on this basis that ADC has been tentatively classified as a subcortical dementia. In this regard, Brouwers et al[18] recently compared the patterns of neuropsychological performance of HIV-infected patients with those of patients with Alzheimer's disease (cortical dementia) and Huntington's disease (subcortical dementia). Discriminant analysis revealed that most patients with HIV were either classified as normal or as having Huntington's disease, while none were classified as having Alzheimer's disease. These results were not secondary to depression in a subset of patients with HIV, since the patients with HIV classified with the patients with Huntington's disease did not differ on the Beck Depression Inventory from those classified as normal. These findings are supported by the work of Van Gorp and colleagues.[19]

In much of the emerging literature on ADC, cognitive impairment is often used synonymously with dementia, with variability across studies both on the criteria for judgment of impairment and the number of affected cognitive domains required for the diagnosis of ADC. A neurobehavioral operational definition of dementia usually includes acquired persistent impairment in at least three of the following spheres of mental activity: psychomotor control, attention and concentration, language, memory, visuospatial skills, emotion, personality, and executive functions such as reasoning or cognitive flexibility. Most of the literature on ADC describes patients with varying degrees of impairment, including patients without a full-blown dementia.

Although research has been considerable on ADC in recent years, the metabolic pathology associated with HIV-related neuropsychiatric impairment is poorly understood. Rottenberg and colleagues[14] studied regional cerebral glucose metabolism with positron emission tomography in nine patients with ADC. They found relative subcortical (thalamus and basal ganglia) hypermetabolism in early ADC, with disease progression accompanied by cortical and subcortical gray matter hypometabolism. Single-photon emission computed tomography of 12 patients with ADC revealed either multiple or focal decreases in blood flow, the latter corresponding to focal neurological signs or symptoms in all but one case.[20] Bottomley et al[21] reported in an abstract that in vivo phosphorus 31 magnetic resonance spectroscopy (MRS) reveals significant reductions in adenosine triphosphate (ATP) and phosphocreatine (PCr) concentrations in eight patients with ADC, compared with control subjects. Finally, Arnold et al[22] reported that patients with a post-viral exhaustion/fatigue syndrome had excessive intracellular acidosis (measured by phosphorus 31 MRS) produced by voluntary exercise of forearm flexor muscle, suggesting that viral infection directly or indirectly produces an impairment of muscle oxidative metabolism. These studies suggest that HIV-related neuropsychiatric impairment may be associated with changes in cerebral blood flow and energy metabolism.

In an effort to further characterize the CNS metabolic alterations associated with HIV-related neuropsychiatric impairment, we utilized in vivo phosphorus 31 MRS. In vivo MRS is used to monitor intracellular metabolites noninvasively and is thought to be free of biological hazard. Moreover, because metabolites may be lost or distorted when tissue is subjected to more traditional biochemical assays such as freeze clamping, MRS may provide a more accurate assessment of concentrations of metabolites free in solution. Phosphorus 31 MRS detects the high-energy phosphates ATP and PCr and their hydrolysis product, inorganic phosphate (Pi). The ratio ATP/Pi is often calculated to indicate the "energy state" of the tissue. Phosphorus 31 MRS also detects signals from phosphodiesters (PDE) and phosphomonoesters (PME), which provide information regarding phospholipid metabolism. Technical advances in recent years enable us to calculate absolute molar concentrations of metabolites from localized volumes of interest (VOIs) in the brain.[23,24]

STUDY 1

This initial study compared a group of HIV-infected men with varying degrees of HIV-related neuropsychiatric impairment with a control group studied previously as part of an effort to determine normal brain metabolite values. All participants gave informed consent after the nature of the study had been fully explained.

Subjects and Methods

Subjects.—The HIV-infected sample consisted of 17 white homosexual men, 32 to 57 years of age, from the Veterans Affairs Medical Center Infectious Disease Clinic, San Francisco, Calif. Seven patients met the criteria for AIDS of the Centers for Disease Control, Atlanta, Ga; eight met the Centers for Disease Control's criteria for ARC; and two patients were HIV seropositive, but asymptomatic. Of the patients with AIDS, four had been diagnosed with *Pneumocystis carinii* pneumonia, two with lymphoma, and one with Kaposi's sarcoma. Patients were excluded from the study if they had a history of recent head injury, seizure disorder, multiple sclerosis, cerebrovascular disease, active opportunistic CNS infection, another known cause for dementia, major psychiatric illness (defined as schizophrenia, major mood disorder, or anxiety disorder), or preexisting organic brain disorder. Two patients were being treated with zidovudine (azidothymidine) alone and 10 patients were being treated with zidovudine plus other antiviral agents such as acyclovir.

The control group consisted of five men and one woman, 29 to 44 years of age, all without a history of recent medical illness, neurological disease, developmental disorder, psychiatric disorder, or substance abuse. No members of the control group belonged to any group at high risk for HIV infection. These subjects had been studied 6 months previously as control subjects in a study of brain tumors.

Assessment of ADC.—All HIV-infected subjects underwent neuropsychological, psychiatric, and neurological examinations. Neuropsychological testing included measurement of orientation, attention, language, spatial construction skills, calculation, reasoning, and memory. Visual motor coordination, motor speed, and grip strength were assessed to appraise perceptual-motor function. All measures were scored using standardized procedures incorporating age and education corrections when such were available for measure. Psychiatric assessment consisted of a structured psychiatric interview, the Brief Psychiatric Rating Scale, Beck Depression Inventory, and the Symptom Checklist-90. The neurological status of each patient was assessed utilizing the AIDS Treatment Evaluation Unit (ATEU) Neuro-AIDS Assessment Form,[25] which provides a more

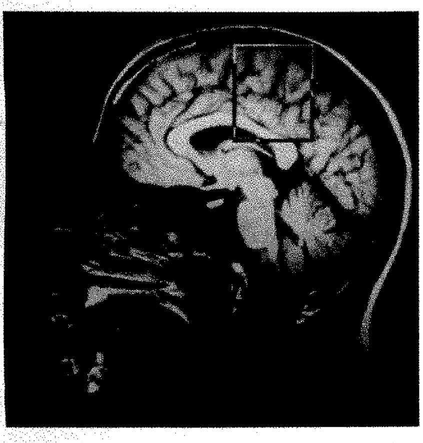

Fig 1.—Sagittal magnetic resonance imaging through the lateral ventricle illustrating the 5 × 5 × 5-cm volume of interest for one of the patients in study 1 who was symptomatic for the human immunodeficiency virus.

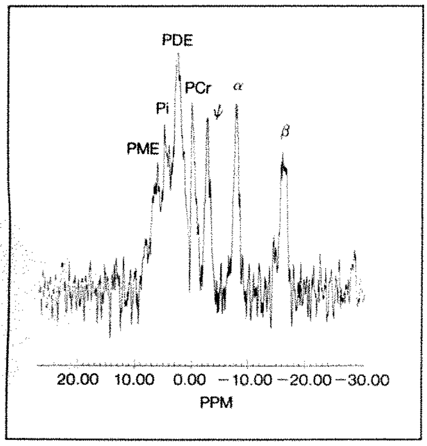

Fig 2.—Illustrative spectrum from the 5 × 5 × 5-cm volume of interest displayed in Fig 1 for a patient who was infected with the human immunodeficiency virus. The letters α, β, and ψ represent the three resonances of adenosine triphosphate, which are averaged to give the concentration of adenosine triphosphate. PME indicates phosphomonoester; Pi, inorganic phosphate; PCr, phosphocreatine; and PDE, phosphodiester.

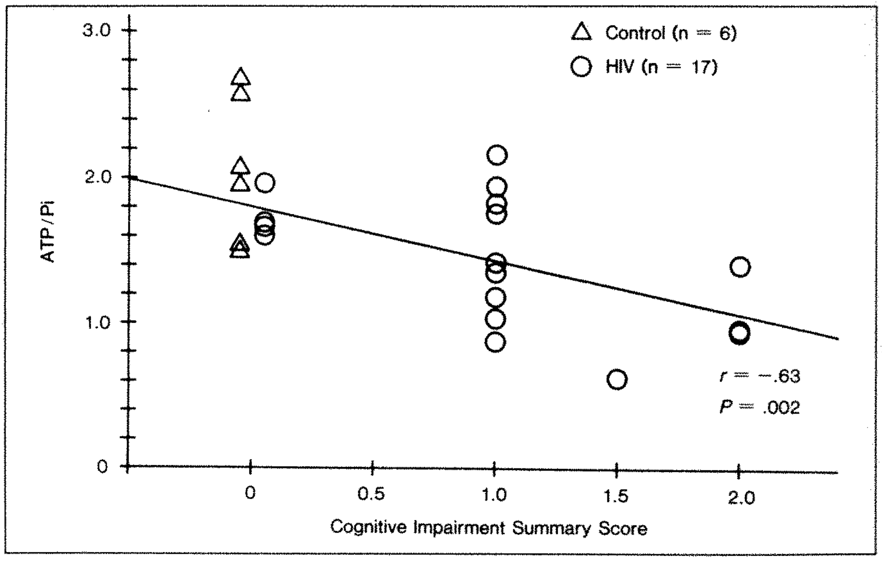

Fig 3.—The ratio of adenosine triphosphate (ATP) to inorganic phosphate (Pi) from the volume of interest vs composite cognitive impairment score is displayed for 17 patients positive for the human immunodeficiency virus (HIV) and six control subjects.

quantitative measure of neurological status than can be obtained from a standard descriptive neurological examination. Utilizing the information obtained from the neuropsychological, psychiatric, and neurological evaluations, each subject was given a summary assessment score for cognitive impairment, behavioral disturbance, and neurological impairment on a four-point scale (0, none; 1, mild; 2, moderate; and 3, severe) utilizing specific parameters established in the ATEU Neuro-AIDS Assessment Form. An overall composite dementia score was then computed for each patient by averaging the cognitive, behavioral, and neurological function summary assessment scores.

MRI and MRS.—All studies were performed in the San Francisco Veterans Affairs Medical Center using a Philips Gyroscan 2.0-T S15 MRI/MRS system. A standard imaging saddle-type proton head coil was used for MRI. For phosphorus 31 MRS, a 16-cm-diameter closely coupled head coil composed of two circular loops was used. Subjects were positioned supine in the magnet with the head inside both coils; the radiofrequency fields of the two coils were orthogonal to each other so that the coils did not interact. A 3-mL external reference of hexamethylphosphorostriamide (HMPT) was positioned in the center of one of the loops of the phosphorus 31 coil. This reference was used (1) to confirm coil position on the magnetic resonance image; (2) to determine the 90° pulse length at the reference position (so that the 90° pulse length at the center of the VOI could be set using a computer-generated B-1 field plot); and (3) as a reference for the relative sensitivity of the loaded coil for the calculation of metabolite concentrations. To accurately select the volume for MRS, T_1 (TR, 600 ms; TE, 30 ms) and T_2 (TR, 2000 ms; TE, 30 and 60 ms)-weighted axial multiple-slice MRIs were obtained. The MRI studies were later blindly rated by a board certified neuroradiologist for any CNS pathologic findings, as well as overall cerebral atrophy, ventricular enlargement, and sulcal enlargement using a four-point rating scale (0, normal; 1, mild; 2, moderate; and 3, severe). The phosphorus 31 coil position was determined through observation of the external standard on the proton image. A 5 × 5 × 5-cm VOI was chosen to coincide with the VOI used in the prior study of brain tumors (which yielded the control data) and is displayed for an illustrative patient study in Fig 1. The magnet was shimmed by observing the proton signal of water (85.9 Hz at 2.0 T) using the proton imaging coil, to a line width of 15 to 25 Hz. The 90° pulse length for phosphorus 31 at the VOI position was determined from the phosphorus 31 signal of the external HMPT reference standard and calculated for the center of the VOI using a computer-generated B-1 field plot. A one-pulse spectrum of the HMPT standard was recorded with a 90° excitation pulse for calibration of the loaded coil sensitivity. Finally, phosphorus 31 spectra were acquired using the improved image-selected in vivo spectroscopy (ISIS) method[26] at 2.0 T. Acquisition parameters were as follows: repetition time, 2 seconds; sweep width, 2 kHz; number of scans, 640; and data size, 1000.

Phosphorus 31 data were processed using the NMR-1 program on a Sun Systems workstation. The broad signal from the less-mobile metabolites was removed by convolution difference and baseline flattening procedures. In addition, an exponential line-broadening factor of 5 Hz was used. Integrals from individual resonance signals were then obtained from least-squares curve-fitted spectra and used for calculation of concentrations[24] and ratios of peak integrals with correction for T_1 saturation.[27] The correction for T_1 saturation is especially important for PCr, for which the pulse repetition time (TR) is less than 2 T_1. For calculation of brain metabolite concentrations in millimoles per liter, an 80% water content was assumed. The metabolites assessed included ATP, Pi, PCr, PME, and PDE. A sample spectrum from a patient with HIV is shown in Fig 2.

pH Measurement.—The pH was calculated from the chemical shift of inorganic phosphate (δPi) referenced to the chemical shift of phosphocreatine (δPCr), which was assumed to be 0 ppm, where δPi and δPCr were obtained from the curve-fitted peak positions:

$$pH = 6.77 + \log(\delta \mathrm{Pi} - 3.29)/(5.68 - \delta \mathrm{Pi})$$

Results

Data were initially analyzed to determine if the 17 HIV-infected patients had different concentrations of high-energy phosphates compared with the normal control subjects. The ATP/Pi ratio in brain was lower for the HIV patients compared with the normal control subjects (1.45 ± 0.45 vs 2.07 ± 0.50, $P = .03$). The absolute magnitude of the difference between groups was the same for the PCr/Pi ratio, but the variance of the ratios was somewhat larger (2.32 ± 0.77 vs 2.96 ± 0.83, $P = .10$). These comparisons were unchanged when examined using nonparametric statistics. These differences between the samples were due to lower ATP and PCr concentrations and slightly higher Pi concentrations in the HIV group, although, because of relatively large between-subject variance of absolute concentrations, none of the absolute concentrations significantly differentiated the samples. There were no significant differences between patients with HIV and control subjects concerning PME or PDE concentrations or the ratios involving these measures.

MRS and Composite Dementia Scores.—When the high-energy phosphates of both the controls and patients with HIV were examined in relationship with the neuropsychiatric summary assessment scores, a number of significant correlations resulted. The ATP/Pi ratio had a significant negative correlation with each of the summary assessment scores ($r = -0.63$, $P = .002$; $r = -.44$, $P = .04$; $r = -.46$, $P = .03$; and $r = -.057$, $P = .005$ for the cognitive, neurological, behavioral, and composite dementia scores, respectively). A scatterplot of the ATP/Pi ratios vs the cognitive impairment summary score is displayed in Fig 3. Comparable significant negative correlations were noted between the PCr/Pi ratios and the summary assessment scores ($r = -.45$, $P = .03$; $r = -.24$, $P = .28$; $r = -.53$, $P = .01$; and $r = -.047$, $P = .03$ for the cognitive, neurological, behavioral, and composite dementia scores, respectively). There were no significant correlations between any of the phospholipid metabolite measures and any of the composite dementia scores.

MRS and Illness Severity.—There were no significant group differences in ATP/Pi or PCr/Pi ratios for patients with AIDS vs patients with ARC. In addition, of nine patients who had CD4 lymphocyte measurements obtained at the time of the study, there were no significant correlations between ATP/Pi or PCr/Pi ratios and absolute CD4 lymphocyte counts. Weight loss was also examined in relation to the ATP/Pi ratio. Three patients had a weight loss of 2.25 kg (5 lb) or greater in the 6 months before enrolling in the study. The ATP/Pi ratio for these patients was 1.51 ± 0.62, which was not significantly different from the corresponding values for the entire ADC group (1.45 ± 0.45).

Cerebral Atrophy.—Eleven of 17 HIV-infected patients had full T_1-weighted MRI studies that were evaluated for evidence of cerebral atrophy and other CNS pathology. Five patients had evidence of atrophy, and no other abnormalities were noted. Measurements of cerebral atrophy were not significantly correlated with the ATP/Pi and PCr/Pi ratios or ATP or PCr concentrations. However, ventricular enlargement was positively correlated with pH ($r = .78$, $P = .007$) and negatively correlated with the PME concentration ($r = -.63$, $P = .038$). Sulcal enlargement scores were positively correlated with the cognitive disturbance summary scores ($r = .66$, $P = .03$).

COMMENT

Although preliminary, the results of study 1 suggest a decrease in brain oxidative metabolism in patients with HIV infection, with the magnitude of the effect directly associated with the magnitude of the patient's neuropsychiatric impairment.

We do not believe that the MRS changes are the result of more cerebrospinal fluid in the brain VOIs of patients with neuropsychiatric impairment because (1) measurements of cerebral atrophy were not significantly correlated with the ATP/Pi or PCr/Pi ratios or ATP concentration; (2) MRS studies of dementias in the elderly do not report decreased ATP/Pi ratios in the presence of cortical atrophy[28]; (3) our examination of two sagittal images through the lateral ventricles in 10 patients in study 1 (the five with the highest and lowest ATP/Pi ratios did not reveal any correlation between the total ventricular and sulcal area within the MRS VOI and the ATP/Pi ratios); and (4) the concentration of Pi in cerebrospinal fluid (0.17 mol/L)[29] is an order of magnitude smaller than the concentration in brain, and the concentration of ATP in cerebrospinal fluid is even smaller; thus, the effect of relatively small differences in the proportion of cerebrospinal fluid in the MRS volume should be to decrease the absolute concentrations, with little, if any, effect on ratios. Finally, although the quantitation of metabolite concentrations requires assumptions regarding the tissue water content, and it is possible that tissue water content differs between groups, such differences would have to affect concentrations of all metabolites equally and could not underlie the specific changes we observed in ATP and PCr concentrations.

Because the 5 × 5 × 5-cm VOI is a heterogeneous volume containing substantial contributions from white matter, gray matter, and ventricular cerebrospinal fluid, and because the weight of histological and neuroimaging studies indicates preferential subcortical involvement by HIV in the CNS, we refined our MRS procedures for study 2 to determine whether the MRS changes are specific to white matter or subcortical gray matter. In addition, preliminary data from our laboratory suggest that phosphorus metabolite concentrations are strongly affected by varying the brain region studied.[30] Thus, we believed that studying more homogeneous VOIs would yield less variable concentration measures across subjects within each group, increasing the statistical power of group comparisons. For study 2, we also selected a more appropriate control group, age and sex matched to the patients with HIV, but with documented HIV seronegativity.

STUDY 2

Subjects and Methods

Subjects.—In the second part of our ongoing study, we have, so far, studied 12 heterosexual male control subjects (mean age ± SD, 24.8 ± 4.4 years) in whom HIV seronegativity was confirmed by HIV-antibody testing (enzyme-linked immunosorbent assay) and three HIV-infected patients with moderate-to-severe neuropsychiatric impairments. All control subjects were examined and found to be cognitively unimpaired using the same neuropsychological battery as used in the examination of the HIV-infected patients. Inclusion and exclusion criteria were as described for study 1 subjects. All three HIV-infected patients carried a diagnosis of ARC, and two patients were receiving zidovudine at the time of study.

MRI and MRS.—Procedures were identical to those described in study 1, except that we selected two different VOIs to better characterize metabolic alterations in subcortical gray matter and white matter. The subcortical gray matter VOI (Fig 4) encompassed the insulae, claustrum, putamen, caudate, globus pallidus, and thalamus bilaterally with minimal white matter contamination. The white matter VOI (Fig 4) encompassed the centra semiovale bilaterally, bordered inferiorly by the inferior margin of the corpus callosum and laterally and superiorly by the inner margin of the cortical mantle. For calculation of brain metabolite concentrations in millimoles per liter, a 72% water content was assumed for the white matter VOI, and an 82% water content was assumed for the gray matter VOI.

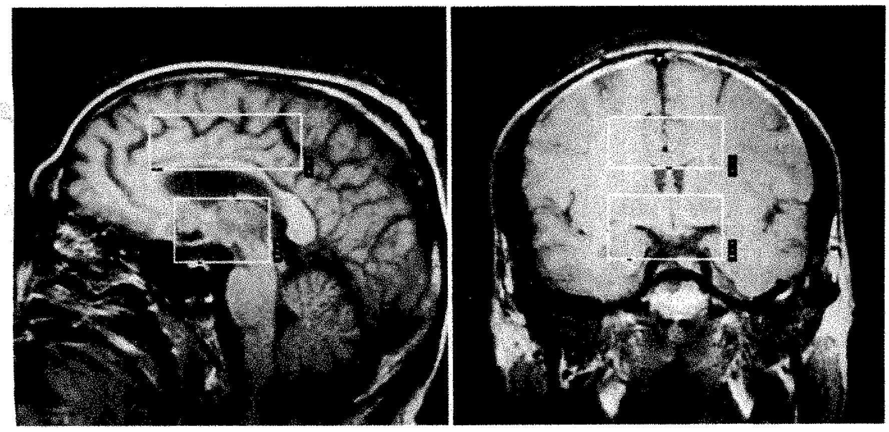

Fig 4.—These two magnetic resonance images illustrate the white matter (outlined in white) and subcortical gray matter (outlined in black) volumes of interest from study 2.

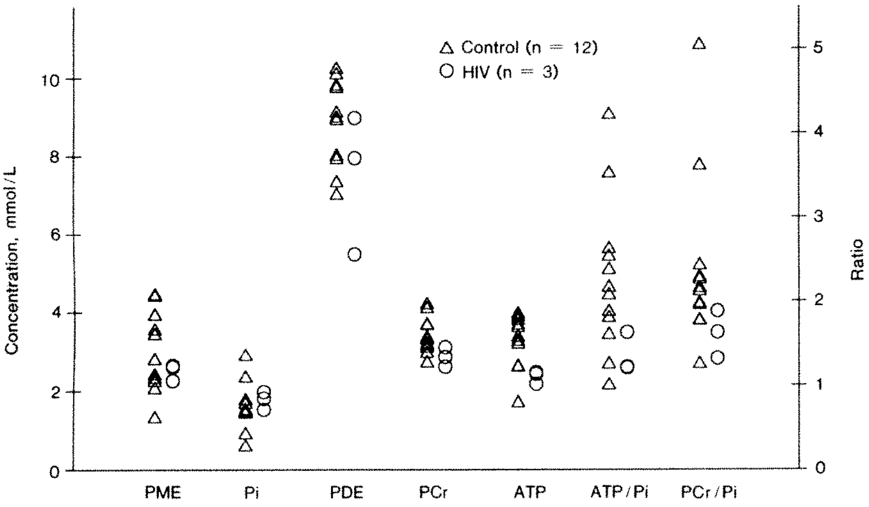

Fig 5.—Phosphorus 31 metabolic concentrations for the white matter volume of interest in Fig 4. PME indicates phosphomonoester; Pi, inorganic phosphate; PDE, phosphodiester; PCr, phosphocreatine; ATP, adenosine triphosphate; and HIV, human immunodeficiency virus.

Results

For the white matter VOI, the HIV-infected patients evidenced decreased ATP and PCr concentrations ($P = .036$ for both, Mann-Whitney *U* test) and trends for decreased ATP/Pi ratios and PCr/Pi ratios ($P = .073$ for both, Mann-Whitney *U* test). Metabolite concentrations and ratios are displayed in Fig 5. For the subcortical gray matter VOI, no differences between the ADC and control groups were apparent on any variables. The SEs of the absolute metabolite concentrations were smaller (about 5% to 7% of the mean value) than were the SEs from the 5 × 5 × 5-cm VOI in study 1.

COMMENT

These preliminary studies strongly suggest that patients with neuropsychiatric impairment secondary to HIV infection of the brain may have impaired brain cellular oxidative metabolism. In study 1, we found that, compared with control subjects, patients with HIV-related neuropsychiatric impairment had significantly reduced brain ATP/Pi ratios and a trend for reduced brain PCr/Pi ratios, with the reduced ratios primarily reflecting reduced ATP and PCr concentrations. These findings are in agreement with the abstract by Bottomley et al[21] that reported significant reductions in ATP and PCr concentrations in eight patients with ADC compared with control subjects. Although our PCr/Pi ratios are higher than those generally reported in the literature, this is because we correct for T_1 saturation. Without the T_1 saturation correction, our PCr/Pi ratio for the control subjects in study 1 is 1.89 ± 0.56, which is in close agreement with that reported by others.[30-32] The correction is important because the long T_1 values for PCr will yield markedly different results if different repetition times are used in various laboratories.

Because of the heterogeneous nature of the study 1 VOIs and evidence from our laboratory that phosphorus metabolite concentrations vary considerably across different brain regions,[33] we selected more homogeneous VOIs for study 2. In study 2, we examined primarily white matter and primarily subcortical gray matter VOIs. Although we studied only three patients for the white matter VOI and two patients for the subcortical gray matter VOI, the decrease in ATP and PCr concentrations appeared to be specific to the white matter VOIs. Although this very preliminary result clearly requires confirmation with a larger sample size, it is in agreement with neurohistological and MRI data revealing major HIV-related neuropathology in white matter.[1,15,16]

The results from study 1 also suggest that the degree of metabolic compromise may be related to the severity of neuropsychiatric impairment, as evidenced by significant negative correlations between the ATP/Pi and PCr/Pi ratios and the neuropsychiatric summary assessment scores. This is the first in vivo MRS study, to our knowledge, to report an association between the severity of HIV-related neuropsychiatric impairment and the degree of impaired brain energy metabolism. This finding is consistent with the results of Pohl et al,[20] who noted that worsening of dementia in patients with ADC was associated with an increase in uptake defects (decreased local cerebral blood flow and disturbed cerebral amine metabolism) on single-photon emission computed tomography. If this association is corroborated by further study, in vivo phosphorus 31 MRS may hold promise for monitoring biological factors associated with HIV disease progression in the brain and for monitoring response to treatment with medications that improve HIV-related neuropsychiatric impairment, such as zidovudine.[34,35]

The association of HIV-related neuropsychiatric impairment with changes in brain high-energy phosphorus metabolism suggests two nonexclusive possibilities. The first is that the metabolic alterations are due to a severe metabolic disturbance in focal areas with the VOI. The second possibility is that the metabolic alterations are due to a process that affects most or all cells within the VOI. To determine if the nature and extent of HIV-related MRS-determined metabolic alterations are due to focal lesions, we are currently attempting to correlate MRI findings (brain atrophy and white-matter disease) with MRS results. If we find that MRS detected changes that occurred in VOIs with absent or very few focal MRI lesions, this will be interpreted to suggest that the metabolic changes are due to a process that affects most cells with the VOI.

It is unclear at this time whether altered brain phosphorus metabolism is specific to HIV disease or is a general finding reflective of a progressive subcortical dementing process. There have been very few in vivo phosphorus 31 MRS studies of subcortical dementia syndromes such as Parkinson's or Huntington's dementia. One small study of Parkinson's disease[28] found no significant differences in the ratios of cerebral phosphate metabolites such as PCr/Pi compared with control subjects. Nevertheless, it is conceivable that our findings of impaired energy metabolism could be the consequence of the subcortical nature of HIV-related neuropsychiatric impairment and would be present in other subcortical dementia syndromes as well. Therefore, we are currently undertaking in vivo phosphorus 31 MRS studies of non-HIV-related subcortical dementias (such as multiple sclerosis-related dementia) to address this issue. In vitro and in vivo phosphorus 31 MRS studies of cortical dementias such as Alzheimer's and multi-infarct dementia have revealed alterations primarily in the PME and PDE resonances with no significant changes in measurements or indexes of cellular oxidative metabolism.[28,36-39]

Our ongoing in vivo phosphorus 31 MRS study of deep white-matter lesions (also called leuko-araiosis) in demented and nondemented elderly subjects also provides interesting comparative data. In white matter VOIs, we have found significant reductions in the ATP/Pi ratios and PDE concentration associated with the presence of extensive deep white-matter lesions, but unrelated to the presence of dementia.[40] In the current study, where many of the HIV-infected patients also have white-matter lesions evidenced on MRI, we find a similar decrease in the ATP/Pi ratio but fail to find a decrease in the PDE concentration. This may indicate that the mechanisms underlying the white-matter changes differ in the two disease processes or may reflect a difference in the severity of disease in the two cases.

This study illustrates the importance of quantitation methodology, along with image-guided three-dimensional localized phosphorus 31 MRS. We used an improved ISIS technique[26] to obtain MRI-localized phosphorus 31 MRS of human brain. This technique, which has been carefully studied in computer-simulated analyses and phantom studies,[24] provides accurate localization for characterization of relatively homogeneous human brain VOIs.

There are a number of simplifying assumptions that, as we have noted previously,[24] are involved in the calculation of molar concentrations. First, for quantitation, the tissue within the VOI is assumed to be homogeneous, with the measured concentrations representing the mean concentration within the VOI. Second, the T_1 values used to calculate concentrations were derived from normal subjects for large brain volumes, which were less homogeneous than the VOIs of the current study. This was necessary because of the tremendously lengthy study times necessary to measure phosphorus 31 T_1 values. We estimated that a T_1 study for each metabolite separately for the white matter and subcortical gray matter VOIs would involve having each subject spend several hours in the magnet for each VOI. Third, our measurements could be influenced by variation between subjects in metabolite mobility as well as in metabolite concentration. Fourth, we assumed a uniform tissue water content for each VOI across subjects. If the water content varied among subjects, that could have affected the concentrations, but it would have affected all metabolites equally.

The simplifying assumptions noted above argue for caution in the interpretation of our results. The results clearly indicate that there are changes in aspects of the phosphorus 31 MRS associated with HIV infection. Although it is possible that the effect reflects differential changes in the mobility of the various metabolites, or in their T_1 values, we do not believe it is likely. Our preliminary simulations suggest that the effect of differences between metabolites in mobility and T_1 values would be small compared with the effect of differences in metabolite concentration (except possibly for PCr, where the T_1 time is greater than the repetition time). Thus, the most parsimonious interpretation of our results is that they reflect concentration differences.

Finally, it is important to note that the in vivo phosphorus 31 MRS technique is in its infancy. We fully expect great advances in magnet strength, pulsing technology, and phosphorus 31 spectroscopic imaging. These advances will result in the ability to quantitate metabolite concentrations throughout the brain in ever smaller voxels. Such advances, together with the development of proton MRS technology, portend an explosion of in vivo studies of brain metabolism in normal and pathological conditions.

The Effect of Sleep on the Dyskinetic Movements of Parkinson's Disease, Gilles de la Tourette Syndrome, Huntington's Disease, and Torsion Dystonia

David R. Fish, MD; Diane Sawyers; Philip J. Allen, MSc; Jeffrey D. Blackie, FRACP; Andrew J. Lees, FRCP; C. David Marsden, FRS

• The effect of sleep on the involuntary movements or dyskinesias in Parkinson's disease, Huntington's disease, primary and secondary torsion dystonia, and Gilles de la Tourette syndrome was studied in a total of 52 patients and 10 normal subjects using video electroencephalographic telemetry. Movements typical of the wake pattern were seen occasionally during unequivocal sleep in all but two completed studies, and in each condition reappeared under similar circumstances. The movements were most likely to occur after awakenings or lightenings of sleep, or in stage one sleep. The movements were very rare during the deeper phases of sleep. Those movements that occurred during sleep without awakenings were usually preceded by arousal phenomena and, rarely, by sleep spindles or slow waves. The control group showed normal "semipurposeful" movements under the same conditions during sleep. The rare appearance of the different dyskinesias and normal movements under similar circumstances during sleep could be a result of common effects on the generator systems or changes in the excitability of the final common motor pathway.

(*Arch Neurol.* 1991;48:210-214)

The widely held belief that most involuntary movements or dyskinesias, except for certain types of myoclonus, cease completely during sleep[1-3] has been shown to be incorrect.[4,5] However, the exact circumstances during sleep under which occasional movements may reappear have not been defined. Unfortunately, previous studies have used inappropriate methods of sleep staging, failed to identify the precise electroencephalographic (EEG) phenomena associated with each movement, or have not characterized the movements themselves.

For the purposes of sleep staging, the overnight record is usually divided into fixed epochs of 20 or 30 seconds.[6] Most epochs contain a mixture of sleep phenomena that may be used to classify each epoch as stages one to four or rapid eye movement (REM) sleep according to the criteria of Rechtschaffen and Kales.[6] However, the fixed-time base employed in this assessment leads to transition epochs that really contain sleep of two different stages. For example, Fig 1 shows a transition from stage two to wake. The first half of the epoch contains sleep phenomena with a low-amplitude submental electromyogram (EMG), background theta activity, and a K complex. Just into the second half of the epoch, alpha rhythm develops. This is followed by a head movement artifact and an increase in submental tone. Conventionally such epochs are scored according to the type of sleep occupying the majority of the period,[6] which, in this case, would be stage two sleep. This approximation has little effect on the overall description of the sleep pattern because transition epochs account for only 3% to 6% of the normal overnight record.[7] However, events that occur in association with changes in sleep stage could be designated inappropriately. Earlier reports[4,8,9] suggest that arousal phenomena frequently precede nocturnal movements. Therefore, studies relying solely on scoring systems such as that described by Rechtschaffen and Kales[6] may be misleading.

The precise EEG phenomena associated with each movement are important because arousals may occur that are insufficient to cause a change in sleep stage,[10] and motor function may vary with specific EEG phenomena. For example, in animals there is a marked reduction in the frequency of spontaneous motor unit discharges in association with sleep spindles,[11] and intracellular recordings in cats have shown rapid changes in the membrane potential of alpha motor neurons during REMs.[12]

Involuntary movements may be identified using surface EMG, but such recordings alone may not distinguish different types of movement. Visual confirmation is often necessary to determine the nature of sleep movements.

In 1964 and 1965, Tassinari et al[4,13] reported the effect of sleep on involuntary movements in several groups of movement disorders. Qualitative direct observations combined with EEG

and EMG recordings suggested that most movements decreased or stopped on falling asleep, but both parkinsonian tremor and "nonrhythmic movements (such as choreic syndromes)" were observed occasionally during all sleep stages, usually in association with awakenings, lightening of sleep, and global or segmental body movements. However, the precise EEG phenomena preceding each type of movement were not described. Subsequently, Mano et al[5] attempted to quantitate the overnight activity of patients with dyskinesias. In four patients with choreoathetosis, one patient with ballismus, and four patients with secondary dystonia, the frequency of "characteristic surface EMG discharges" showed a reduction from wake through stages one to four with stage REM giving a level similar to that of stage one or two sleep.

The findings of Tassinari et al[4,13] and Mano et al[5] have been supplemented by investigations that have been limited to a single-movement disorder, although methodological differences impair direct comparisons. Parkinsonian tremor has been extensively studied during sleep, but the results have been conflicting. Parkinson himself observed that tremor could occur during sleep in advanced cases of the shaking palsy,[14] and this was supported by Gowers,[15] but both Froment and Delore[16] and Friedlander[17] failed to observe tremor during sleep in such patients. Accelerometer recordings, however, confirmed the occurrence of tremor during sleep in Parkinson's disease, particularly in association with awakenings or body movements, and showed brief bursts of tremor during stage REM sleep.[8,9] The occurrence of parkinsonian tremor during non-REM sleep in the absence of behavioral or EEG evidence of arousal has also been reported,[8] although not confirmed by Stern et al[9] who noted the appearance of posterior alpha rhythm prior to episodes of tremor during epochs of sleep that were scored as stage two. The amplitude of tremor during sleep was observed to be half to two thirds that of wake,[9] and to show marked beat-to-beat variation (particularly in stage REM sleep), although the frequency was unchanged.[8,9] With regard to dystonia, brief bursts of asymmetrical sternocleidomastoid surface EMG activity were recorded during stage REM sleep in eight of 16 patients with spasmodic torticollis.[18] In Gilles de la Tourette syndrome surface EMG, accelerometer, and video recordings demonstrated tics during all sleep stages in 10 children or young adults.[19] The mean number of tics per night during sleep was only 12, and the proportion of tics occurring in each sleep stage was not determined. No tics were recorded during sleep in two older subjects (aged 37 and 48 years) with this syndrome.

The present study investigated the effect of sleep on the expression of parkinsonian tremor, Huntington's disease, Gilles de la Tourette syndrome, primary and secondary torsion dystonia, and "semipurposeful" global or gestural movements in normal subjects.

SUBJECTS AND METHODS

Subjects

Sixty-two subjects were studied (Table 1) with the approval of the Medical Ethics Committee of The National Hospital for Neurology and Neurosurgery Diseases, London, England. No alterations were made to treatment, and all subjects gave informed consent. Thirty-seven of the patients were taking medication. These included 14 patients who were taking benzodiazepines, 15 who were taking anticholinergics, 11 who were taking dopaminergic drugs, and 10 who were taking antidopaminergic drugs. One patient with Parkinson's disease had previously undergone a unilateral thalamotomy (ipsilateral to the limb studied), and two patients with primary torsion dystonia had had bilateral thalamotomies.

Methods

Sleep studies were performed in a quiet single room after one night of adaptation using the split-screen video cable EEG telemetry equipment described by Roberts and Fitch.[20] This provided up to nine channels of electrophysiological monitoring in addition to the time code. Six channels were used to record sleep following the recommendations of Rechtschaffen and Kales,[6] and up to three were used to record movements. Movements were monitored using surface EMG pad electrodes 1.5 cm in diameter or accelerometer (Siemens type 230) recordings from appropriate muscle groups, and a low light-intensity video camera. The paper records were coded and scored blind to the clinical information by one of us (D.R.F.) using the recommendations of Rechtschaffen and Kales[6] with the following amendments to describe transition epochs: lightening (L), an epoch that contained a transition from a deeper stage to a lighter stage of sleep; awakening (A), an epoch that contained a transition from sleep to wake; deepening (D), an epoch that contained a transition from a lighter stage to a deeper stage of sleep; and predormitory (P), an epoch that contained a transition

from wake to sleep.

The entire split-screen video recording displaying the neurophysiological data and simultaneous clinical events was reviewed in all cases, and the times of all definite movements were noted. Epochs of awakening or lightening that included a movement were reexamined without reference to the video or movement detector channels in order to determine whether the change in sleep stage preceded or followed the movement.

The onset of each movement that occurred during unequivocal sleep was marked on the paper record after it had been ascribed to a sleep stage. Two randomly timed control marks were then made on the paper record for each movement.

The two-second "miniepoch" prior to each mark was subsequently analyzed blind to the movement channels or video recording for the following phenomena: (1) arousal phenomena: (*a*) increased submental tone above 50% of the baseline and increase in EEG frequency, or (*b*) alpha band rhythm lasting for more than 0.5 second (outside stage REM sleep unless associated with other evidence of arousal), or (*c*) K complex; (2) sleep spindles (11.5 to 15 Hz activity for at least 0.5 second); (3) slow waves (greater than 75 μV peak-to-peak amplitude); and (4) REMs.

This miniepoch length was the shortest needed to readily detect all of the above phenomena. Furthermore, a study of sleep spindles and muscle discharges in rats showed a disparity of up to 1.5 seconds between the onset of a sleep spindle and associated changes in muscle activity.[11] If two or more phenomena occurred together (which happened in less than 5% of events) only the one occupying most of the miniepoch was counted.

The relative risk of a specific EEG phenomena preceding a particular movement was defined as

$$\frac{\text{Percent Premovement Miniepochs Containing the Phenomena}}{\text{Percent Control Miniepochs Containing the Phenomena}}$$

Two hundred eighty-three miniepochs from four randomly selected records were scored by two observers independently (D.R.F. and D.S.) with interobserver and intraobserver repeatabilities of 0.90 and 0.96, respectively.

RESULTS

The Number of Movements During Unequivocal Sleep

Nine patient and two control studies were abandoned because of an inadequate video or neurophysiological record. Movements typical of the wake dyskinesia were documented during unequivocal sleep in 41 of 43 completed studies (Table 2). Control subjects often made apparently normal semipurposeful movements during sleep.

The Reappearance of Movements in Relation to Sleep Stage

Normal Semipurposeful Movements in Control Subjects.—These movements were most frequent during awakenings or lightenings of sleep, and then stage one sleep. They were rare during stages two and REM (Table 3), and virtually absent during stages three, four, predormitory, and deepening (median scores zero in all four of these categories). The voluntary control of such movements precluded a meaningful assessment of the frequency during wakefulness.

Dyskinesias in Patients With Movement Disorders.—The number of epochs that contained a movement per 100 epochs of each sleep stage showed a similar pattern for all dyskinetic groups (Table 4). All types of movements were most frequent during stage awakening, followed by stages lightening and one. The movements reoccurred very occasionally in some patients during stages two and REM, and were virtually absent during slow-wave sleep, predormitory, or deepening (the median scores were zero for these four categories, with the exception of stage predormitory in patients with Gilles de la Tourette syndrome, which had a score of 2.3 movements per 100 epochs).

The Rank Order of Sleep Stages by the Frequency of Movements

Ranking of sleep stages by the proportion of epochs containing a movement showed no significant difference between the various dyskinetic groups (F = 1.000, analysis of variance [ANOVA]). The rankings were combined to give a mean rank order of sleep stages by the proportion of epochs containing a movement. Each of the following differences was significant (*P* < .05, ANOVA Duncan): Wake greater than awakening greater than lightening greater than stage 1 greater than stage 2 greater than stage REM greater than stages 3, 4, or D. Stages 3, 4, and D did not show a significant difference between each other. Stage P was less than stage 2, greater than stage 3, 4, or D, and not significantly different from stage REM.

The Timing of Movements in Relation to Awakenings and Lightenings of Sleep

Dyskinetic movements during epochs of awakening or lightening usually occurred after the onset of the change in the depth of sleep (Table 4).

The Specific EEG Phenomena Preceding Movements

All types of movement were most likely to occur after EEG evidence of arousal. Conversely, they were less likely to occur in association with sleep spindles and slow waves (Table 5).

Observations on the Consecutive Occurrence of Different Movement Conditions

Normal semipurposeful global or gestural movements were seen during the 20-second epoch before 28% of dyskinetic movements. Two patients had periodic movements of sleep and Parkinson's disease. Both cases had episodes of hand tremor that commenced during a triple flexion of a lower limb (Fig 2). On the few occasions that dyskinetic movements were manifest during epochs staged as REM sleep, they were usually preceded by a fragmentary myoclonic twitch or burst of submentalis activity (Fig 3).

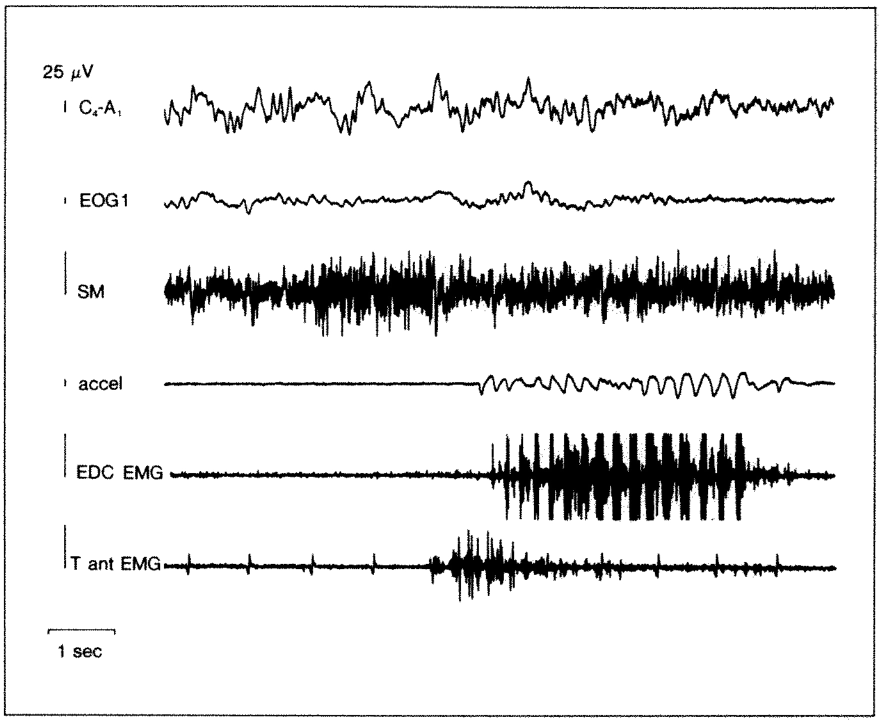

Fig 2.—An episode of parkinsonian tremor evident in the accelerometer (accel) and extensor digitorum communis (EDC) records during a lightening of sleep, preceded by evidence of arousal (K complex and increase in submental electromyogram [EMG]) and associated with a periodic movement of sleep at the onset evident in the tibialis anterior EMG (T ant EMG). REOG indicates right electro-oculogram; LEOG, left electro-oculogram; SM, submentalis surface EMG.

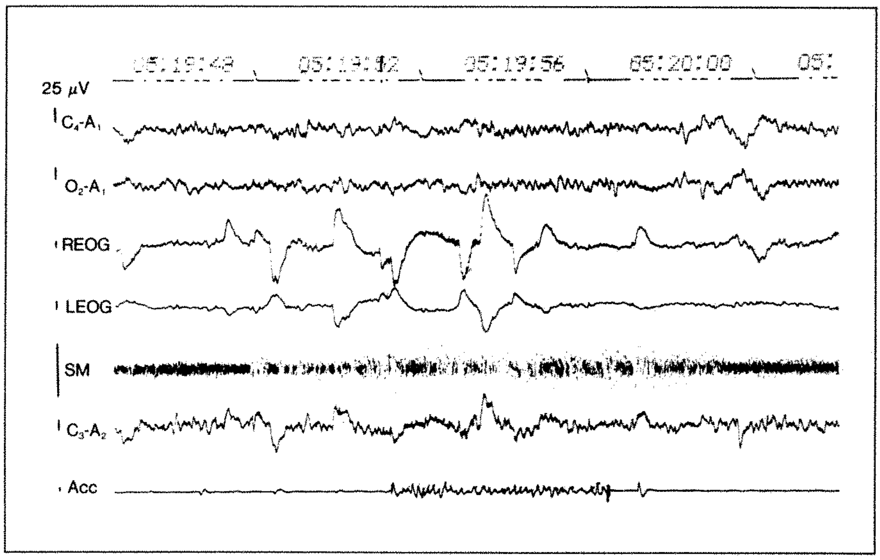

Fig 3.—An episode of tremor in a patient with Parkinson's disease during an epoch of stage rapid eye movement sleep seen in the accelerometer (Acc), and preceded by bursts of submentalis activity evident in the submental electromyographic recording. REOG indicates right electro-oculogram; LEOG, left electro-oculogram; and SM, submentalis surface electromyogram.

Observations on the Morphology of Movements in Sleep

All movements recorded by camera should have been visible to an observer from the end of the bed. Most dyskinetic movements during sleep were briefer or fragmented and of less amplitude than typical wake movements.

COMMENT

Nearly all patients with Parkinson's disease, Huntington's disease, dystonia, or Gilles de la Tourette syndrome displayed movements characteristic of the wake condition during sleep. Parkinsonian tremor, chorea, dystonic spasms, and tics all reappeared occasionally during sleep under similar circumstances. These dyskinesias occurred most commonly after an awakening and, to a lesser extent, following a shift to a lighter sleep stage or during stage one sleep. These dyskinesias were very rare during epochs staged as sleep stages two or REM, while the total number recorded during stages predormitory, deepening, three, and four was negligible. The conventional 20- or 30-second sleep staging epoch is long relative to the duration of these nocturnal movements and even the use of additional terms to describe transition epochs may not fully describe the relationship of brief movements to sleep activities such as miniarousals or other body movements. This study demonstrated that movements occurring in unequivocal sleep usually followed a 2-second epoch that contained EEG evidence of arousal. Conversely, the movements very rarely occurred in association with slow waves or sleep spindles. The latter finding is in keeping with the report of reduced motor unit activity during sleep spindles in rats.[11]

Semipurposeful movements occurred in normal subjects in the same sleep stages and in association with the same EEG phenomena as the dyskinesias. These observations suggest that both normal semipurposeful sleep movements and dyskinesias are markedly suppressed during the deeper phases. Conversely, they all reappear during awakenings, lightenings of sleep, or stage one sleep. Presumably the normal movements and dyskinesias that were studied are all generated in the brain, but it is unlikely that they arise in the same cerebral region. It is possible that sleep silences the cerebral generators in different brain regions. Alternatively, it may inactivate an output pathway from the brain to the muscles common to all these types of movement. The latter would be supported by the variety of motor behaviors that are released during REM sleep following damage to the descending inhibitory pathways arising in the region of the locus coeruleus in animals,[21] and in some patients with brain-stem disorders.[22,23] Further studies on the overall excitability of the corticospinal tract during sleep may help to clarify the nature of these mechanisms.

When the world turns upside down...

Transderm Scōp is the better choice for motion sickness prevention

- more effective than 25 mg meclizine and Dramamine®[1,2]
- better compliance because transdermal delivery is more convenient

Transderm Scōp®
scopolamine
programmed delivery
0.5 mg over 72 hrs

Transderm Scōp should not be used in children. Use with special care in the elderly and in patients taking drugs (including alcohol) capable of causing CNS effects. Dryness of the mouth occurs in about two thirds of people. Please see Prescribing Information on next page before prescribing.

CIBA

Transderm Scōp®

scopolamine
(formerly Transderm-V)

Transdermal Therapeutic System

Programmed delivery *in vivo* of 0.5 mg of scopolamine over 3 days

BRIEF SUMMARY (FOR FULL PRESCRIBING INFORMATION, SEE PACKAGE INSERT)

INDICATIONS AND USAGE

Transderm Scōp is indicated for prevention of nausea and vomiting associated with motion sickness in adults. The disc should be applied only to skin in the postauricular area.

Clinical Results: Transderm Scōp provides antiemetic protection within several hours following application of the disc behind the ear. In 195 adult subjects of different racial origins who participated in clinical efficacy studies at sea or in a controlled motion environment, there was a 75% reduction in the incidence of motion-induced nausea and vomiting. Transderm Scōp provided significantly greater protection than that obtained with oral dimenhydrinate.

CONTRAINDICATIONS

Transderm Scōp should not be used in patients with known hypersensitivity to scopolamine or any of the components of the adhesive matrix making up the therapeutic system, or in patients with glaucoma.

WARNINGS

Transderm Scōp should not be used in children and should be used with special caution in the elderly. See **PRECAUTIONS.**

Since drowsiness, disorientation, and confusion may occur with the use of scopolamine, patients should be warned of the possibility and cautioned against engaging in activities that require mental alertness, such as driving a motor vehicle or operating dangerous machinery.

Potentially alarming idiosyncratic reactions may occur with ordinary therapeutic doses of scopolamine.

PRECAUTIONS

General

Scopolamine should be used with caution in patients with pyloric obstruction, or urinary bladder neck obstruction. Caution should be exercised when administering an antiemetic or antimuscarinic drug to patients suspected of having intestinal obstruction.

Transderm Scōp should be used with special caution in the elderly or in individuals with impaired metabolic, liver, or kidney functions, because of the increased likelihood of CNS effects.

Information for Patients

Since scopolamine can cause temporary dilation of the pupils and blurred vision if it comes in contact with the eyes, patients should be strongly advised to wash their hands thoroughly with soap and water immediately after handling the disc.

Patients should be advised to remove the disc immediately and contact a physician in the unlikely event that they experience symptoms of acute narrow-angle glaucoma (pain in and reddening of the eyes accompanied by dilated pupils).

Patients should be warned against driving a motor vehicle or operating dangerous machinery. A patient brochure is available.

Drug Interactions

Scopolamine should be used with care in patients taking drugs, including alcohol, capable of causing CNS effects. Special attention should be given to drugs having anticholinergic properties, e.g., belladonna alkaloids, antihistamines (including meclizine), and antidepressants.

Carcinogenesis, Mutagenesis, Impairment of Fertility

No long-term studies in animals have been performed to evaluate carcinogenic potential. Fertility studies were performed in female rats and revealed no evidence of impaired fertility or harm to the fetus due to scopolamine hydrobromide administered by daily subcutaneous injection. In the highest-dose group (plasma level approximately 500 times the level achieved in humans using a transdermal system), reduced maternal body weights were observed.

Pregnancy Category C

Teratogenic studies were performed in pregnant rats and rabbits with scopolamine hydrobromide administered by daily intravenous injection. No adverse effects were recorded in the rats. In the rabbits, the highest dose (plasma level approximately 100 times the level achieved in humans using a transdermal system) of drug administered had a marginal embryotoxic effect. Transderm Scōp should be used during pregnancy only if the anticipated benefit justifies the potential risk to the fetus.

Nursing Mothers

It is not known whether scopolamine is excreted in human milk. Because many drugs are excreted in human milk, caution should be exercised when Transderm Scōp is administered to a nursing woman.

Pediatric Use

Children are particularly susceptible to the side effects of belladonna alkaloids. Transderm Scōp should not be used in children because it is not known whether this system will release an amount of scopolamine that could produce serious adverse effects in children.

ADVERSE REACTIONS

The most frequent adverse reaction to Transderm Scōp is dryness of the mouth. This occurs in about two thirds of the people. A less frequent adverse reaction is drowsiness, which occurs in less than one sixth of the people. Transient impairment of eye accommodation, including blurred vision and dilation of the pupils, is also observed.

The following adverse reactions have also been reported on infrequent occasions during the use of Transderm Scōp: disorientation; memory disturbances; dizziness; restlessness; hallucinations; confusion; difficulty urinating; rashes and erythema; acute narrow-angle glaucoma; and dry, itchy, or red eyes.

Drug Withdrawal: Symptoms including dizziness, nausea, vomiting, headache and disturbances of equilibrium have been reported in a few patients following discontinuation of the use of the Transderm Scōp system. These symptoms have occurred most often in patients who have used the systems for more than three days.

OVERDOSAGE

Overdosage with scopolamine may cause disorientation, memory disturbances, dizziness, restlessness, hallucinations, or confusion. Should these symptoms occur, the Transderm Scōp disc should be immediately removed. Appropriate parasympathomimetic therapy should be initiated if these symptoms are severe.

DOSAGE AND ADMINISTRATION

Initiation of Therapy: One Transderm Scōp disc (programmed to deliver 0.5 mg of scopolamine over 3 days) should be applied to the hairless area behind one ear at least 4 hours before the antiemetic effect is required. Only one disc should be worn at any time.

Handling: *After the disc is applied on dry skin behind the ear, the hands should be washed thoroughly with soap and water and dried. Upon removal of the disc, it should be discarded, and the hands and application site washed thoroughly with soap and water and dried, to prevent any traces of scopolamine from coming into direct contact with the eyes. (A patient brochure is available.)*

Continuation of Therapy: Should the disc become displaced, it should be discarded, and a fresh one placed on the hairless area behind the other ear. If therapy is required for longer than 3 days, the first disc should be discarded, and a fresh one placed on the hairless area behind the other ear.

The system should be stored between 59°-86°F (15°-30°C).

CAUTION

Federal law prohibits dispensing without prescription.

Intravenous Immunoglobulin Treatment in Patients With Chronic Inflammatory Demyelinating Polyneuropathy

Clinical and Laboratory Characteristics Associated With Improvement

P. A. van Doorn, MD; M. Vermeulen, MD; A. Brand, MD; P. G. H. Mulder, PhD; H. F. M. Busch, MD

• Of 52 patients fulfilling the criteria of chronic inflammatory demyelinating polyneuropathy, 20 (38%) did not improve after intravenous immunoglobulin treatment, two (4%) had a short-lasting improvement and subsequent infusions had no effect, nine (17%) reached a spontaneously or therapeutically induced complete remission, and 21 patients (40%) needed intermittent infusions to maintain improvement. All patients who improved initially had symptoms that significantly interfered with life-style. After treatment, 90% of these patients were independent in their daily activities. Significantly associated with improvement were disease duration of less than 1 year, progression of weakness until treatment, absence of discrepancy in weakness between arms and legs, areflexia of the arms, and slowed nerve conduction velocity of the motor median nerve. The probability of improvement if all these features are present is 93%.

(*Arch Neurol.* 1991;48:217-220)

Patients with chronic inflammatory demyelinating polyneuropathy (CIDP) may respond to corticosteroids[1] and to plasma exchange,[2] which was shown in controlled studies. Improvement has also been reported after the administration of azathioprine,[3,4] cyclophosphamide,[4,5] and cyclosporine A.[6-8] Recently, several uncontrolled studies described a beneficial response to intravenous immunoglobulin (Ig) treatment.[9-13] The beneficial effect of intravenous Ig treatment in patients with CIDP was supported by the results of a double-blind placebo-controlled crossover study.[14]

In this article, we present our experience with intravenous Ig treatment in 52 patients with CIDP. The aims of this study were to investigate what the proportion of CIDP patients is that improved after intravenous Ig treatment, what the effect of repeated intravenous Ig is on the disability of these patients, and which clinical and routine laboratory factors are associated with improvement.

PATIENTS AND METHODS

Patients

Clinical and laboratory records were reviewed for all patients who were judged to have a CIDP and who were treated with intravenous Ig.

All patients included in this study fulfilled the following criteria as outlined by Dyck et al[15]: (1) the course of the disease may be steadily progressive, chronic monophasic, or recurrent; (2) nerve conduction may be normal in motor and afferent fibers, but more commonly (though not mandatory) it is slowed; (3) cyto-albuminologic dissociation is usually seen at some time during the course of the disease and in most of our patients; and (4) had a tendency to symmetric involvement and to involvement of proximal as well as distal limb muscles.

We tried to exclude patients with the Guillain-Barré syndrome,[16] therefore all patients had the clinical features of a polyneuropathy with a progression of weakness of at least 2 months. Patients with known systemic disease were excluded in our series, except for four patients with diabetes mellitus and two patients with a benign monoclonal gammopathy, type IgG-κ and IgG-λ, respectively.

Clinical Assessment

Muscle strength was tested manually using the Medical Research Council scale.[17] At least six muscle groups were tested on each side. These were muscles for shoulder abduction, elbow flexion, wrist extension, hip flexion, knee extension, and ankle dorsiflexion. Asymmetric weakness between left and right was defined as a difference of two or more grades on the Medical Research Council scale between at least one of the same muscle groups. Discrepancy in weakness between arms and legs was defined as a difference in muscle strength of two or more grades on the Medical Research Council scale between ankle dorsiflexion and wrist extension.

The disability of the patients was assessed using the Rankin scale.[18] This scale estimates functional disability or handicap. Improvement was defined as an increase of at least one step on the Rankin disability scale.

Treatment

All 52 patients with CIDP were treated with high-dose intravenous immunoglobulin (Central Laboratory of the Dutch Red Cross Blood Transfusion Service, Amsterdam, the Netherlands) in a dosage of 0.4 g/kg of body weight per day for five consecutive days. If necessary, treatment was repeated. The 52 patients did not receive corticosteroids or other immunosuppressive treatment within the 2 months before, or together with, intravenous Ig treatment.

Statistical Analysis

We investigated the association between improvement and the following characteristics: sex, age less than 50 years, disease duration less than 1 year, absence of asymmetric weakness, absence of discrepancy in weakness between arms and legs, areflexia legs, areflexia arms, progression of weakness until 4 weeks or less before onset of treatment, remitting or progressive course of the disease, cerebrospinal fluid protein level of more than 0.5 g/L in adults or more than 0.4 g/L in children, a cerebrospinal fluid white blood cell count of 10.10^6/L or less, and slowed nerve conduction velocity (NCV) of the motor median nerve. The NCV of the median nerve was measured over the forearm with standard techniques, slowed NCV was defined as an NCV of less than 80% of the lower limit of normal. The lower limit of normal was 51 m/s.

For analysis of the association between each of the above-mentioned characteristics and improvement after intravenous Ig treatment, the two-sided Fisher Exact Probability Test was used. A logistic regression analysis was used for simultaneously analyzing the predictive value of all those characteristics that were significantly related with improvement.

RESULTS

Fifty-two patients (33 men and 19 women) were diagnosed as having

CIDP over a study period of 8 years. Their ages ranged from 5 to 82 years (mean, 48 years) at onset of CIDP in the group of patients who improved, and from 10 to 76 years (mean, 46 years) in the group of patients who did not improve.

The mean follow-up in the group of patients who improved was 4.1 years, median, 3.1 years (range, 8 to 251 months). The mean follow-up in the group of patients who did not improve was 5.7 years, median, 3.6 years (range, 16 to 295 months). Before intravenous Ig was started, nine (17%) of 52 patients had remissions and exacerbations. The mean and median time between onset of CIDP and intravenous Ig treatment in the patients with a remitting course was 9 months (range, 4 to 18 months). The mean time between onset of CIDP and intravenous Ig treatment in the patients with the progressive form was 25 months, median time, 6 months (range, 2 to 247 months). The group of patients with a remitting course has a mean age of 36 years, median, 31 years (range, 10 to 64 years). The patient group with the progressive form has a mean age of 49 years, median, 54 years (range, 5 to 82 years). Follow-up revealed lung cancer in two patients; in one patient, 6 months, in the other patient, 2 years after the diagnosis of CIDP was made and intravenous Ig was started. The second patient died. One patient died of a mesothelioma after 6 years of intravenous Ig treatment. Two patients died after a myocardial infarction, and one patient died of complications after abdominal surgery; these three patients received intravenous Ig for a period of 2 to 3 years. All six patients had improved after treatment with intravenous Ig, one had a remission after one treatment course, the other five needed repeated infusions to maintain the improved condition.

Treatment Response

Thirty-two (62%) of the 52 patients improved after treatment with intravenous Ig. The improved condition could be maintained in 30 (94%) of these patients for a mean follow-up period of 4 years. There was no correlation between the course of CIDP (remitting or progressive) and improvement after treatment with intravenous Ig. The mean time after onset of intravenous Ig treatment to the initial signs of improvement was 5 days (range, 3 to 8 days). The mean time to reach maximal improvement was 5 weeks (range, 2 to 16 weeks).

The disability before treatment and the maximal score after treatment was measured with the Rankin score (Table 1).

Table 1.—Minimal and Maximal Clinical Grade in 32 Patients With CIDP Who Improved After Intravenous Immunoglobulin (Ig) Treatment*

Rankin Score		Intravenous Ig Treatment, No. of Patients	
Level	Description	Before	After
0	Asymptomatic	. . .	7
1	Nondisabling symptoms that do not interfere with life-style	. . .	18
2	Minor disability symptoms that lead to some restriction of life-style, but do not interfere with the patients' capacity to look after themselves	. . .	4
3	Moderate disability symptoms that significantly interfere with life-style or prevent totally independent existence	12	3
4	Moderately severe disabiilty symptoms that clearly prevent independent existence, although patient does not need constant attention day and night	13	. . .
5	Severely disabled, totally dependent, requiring constant attention day and night	7	. . .

*CIDP indicates chronic inflammatory demyelinating polyneuropathy.

Four patients improved one grade, 10 patients improved two grades, eight patients improved three grades, and 10 patients improved four grades on the Rankin scale. Twenty-one (66%) of the 32 patients who improved (40% of all 52 patients) needed intermittent intravenous Ig treatment to maintain the maximal level of improvement. Initially, most of these patients received 0.4 g of intravenous Ig per kilogram of body weight every other week. In nine of these 21 patients, the dosage of intravenous Ig could gradually be tapered off to an average dosage of 0.25 g of intravenous Ig per kilogram of body weight every other week, without clinical signs of relapse. This maintenance therapy of intravenous Ig was administered within 1.5 hours in an outpatient department.

In two of 32 patients, there was a short-lasting improvement (±3 weeks), and subsequent intravenous Ig infusion had no effect. Nine (22%) of the 32 patients who improved reached complete remission (17% of all patients). The median follow-up in patients in remission was 24 months (range, 6 to 68 months). The only differences between patients who reached complete remission and the other patients who improved was the disease duration before treatment.

The median time from the first signs of CIDP to the onset of intravenous Ig treatment in the patients who reached complete remission was 3 months (range, 2 to 8 months), whereas the median time was 7 months (range, 2 to 220 months) in the group of patients who improved, but who needed intermittent intravenous Ig treatment.

Side Effects of Intravenous Ig Treatment

Minor side effects such as headache, nausea, and fatigue were sometimes observed, mainly related to the speed of infusion. None of the patients developed hepatitis. Ten patients who had intermittent intravenous Ig infusions for at least 2 years were tested for the presence of human immunodeficiency virus; all were negative.

Laboratory Data

The mean conduction velocity of the motor median nerve was 27 m/s (range, 6 to 58 m/s) in the group of patients who improved, and 44 m/s (range, 11 to 61 m/s) in patients without improvement. The mean cerebrospinal fluid protein level was 1.08 g/L (range, 0.35 to 3.41 g/L) in the group with improvement, and 1.10 g/L (range, 0.33 to 3.44 g/L) in the group without improvement. The mean number of cells in the cerebrospinal fluid in both groups was 5×10^6/L, the range in the group with improvement varied between 0 and 20×10^6/L, in the group without improvement it varied between 0 and 27×10^6/L.

Factors Associated With Improvement

Table 2 shows that five factors were significantly associated with improvement as follows: disease duration of less than 1 year, progression of weakness until approximately 4 weeks before onset of treatment, absence of

Table 2.—Clinical and Laboratory Characteristics Associated With Improvement After Intravenous Immunoglobulin (Ig) Treatment in 52 Patients With CIDP*

Descriptor	Improved After Intravenous Ig: Yes (n = 32), No. (%)	Improved After Intravenous Ig: No (n = 20), No. (%)	P†

†Fisher's Exact Test; two-sided.

Table 3.—Logistic Regression Model for Chance of Improvement After Intravenous Immunoglobulin (Ig) Treatment*

Factor		Odds Ratio	Logistic Coefficient	P
Absence of discrepancy in weakness between arms and legs	(a)	6.664	1.897	.076
Disease duration <1 y	(b)	6.234	1.830	.041
Areflexia, arms	(c)	4.138	1.420	.102
Nerve conduction velocity in motor median nerve <80% of normal	(d)	3.284	1.189	.199

*Probability of responding to intravenous Ig if factors a, b, c, and d are all present = $1/(1 + e^{-y}) = 0.93$. $y = C_o + C_a + C_b + C_c + C_d = 2.556$. C_o = constant term = −3.780. $C_{a,b,c,d}$ are the logistic coefficients of factors a, b, c, and d.

discrepancy in weakness between arms and legs, areflexia of the arms, and slowed NCV of the motor median nerve over the forearm.

Since the factor "progression of weakness until onset of treatment" was required for improvement, we excluded this factor from further analysis.

Using logistic regression, the other four factors significantly associated with improvement were analyzed and the predictive value of these factors combined was calculated (Table 3). This table shows that if the factors absence of discrepancy in weakness between arms and legs, disease duration less than 1 year, areflexia of the arms, and slowed NCV over the motor median nerve are present, the estimated probability of improvement is 93%. If none of these factors is present, the estimated probability is 2%.

The first two factors are the strongest predictive factors, but the last one "slowed motor median NCV" still has a clinically relevant contribution to the probability of improvement, since the odds ratio is 3.284.

Patients Without Improvement

Twenty (38%) of 52 patients with CIDP did not improve after intravenous Ig treatment. Fifteen of these 20 patients were treated with prednisone, and five improved. After tapering off prednisone, one of these five patients was treated with azathioprine, which was followed by improvement. Five patients were not treated with prednisone; one patient showed a slow spontaneous improvement without further treatment, and the four other patients were not treated with prednisone because side effects were feared. One of the two patients with short-lasting improvement after treatment with intravenous Ig had a favorable response to prednisone. The second patient did not respond to treatment with prednisone, azathioprine, or cyclophosphamide. This patient improved after plasma exchange and treatment with cyclosporine A. After 3 years, this patient is in Rankin scale three.

We reviewed the case records and the follow-up information of the 20 patients who had not improved after intravenous Ig, and tried to find a diagnosis other than CIDP. Two patients might have a polyneuropathy of the type as described by McLeod et al,[20] and one patient might have vasculitis limited to the peripheral nervous system.[21] In two patients the polyneuropathy was associated with mild diabetes mellitus and in one patient with alcohol abuse. Three patients had a polyneuropathy that could have been initially a neuropathy as described by Pestronk et al[22]; in the serum samples of these three patients high titers of anti-GM_1 antibodies were demonstrated. In one patient a hereditary polyneuropathy was likely. In the 10 other patients, no diagnosis could be established other than CIDP.

COMMENT

This study shows that 38% of patients judged to have a CIDP did not improve after treatment with intravenous Ig. A further 4% had a short-lasting improvement and subsequent infusions had no effect. A complete remission was reached by 17% of patients, which might have been caused by treatment, but spontaneous remissions do occur and some patients may have had a Guillain-Barré syndrome-like course even after progression of more than 8 weeks. Especially in this group of patients it is difficult to decide whether or not these patients had responded to treatment. A beneficial treatment response is more likely in the patients (40%) who improved after treatment with intravenous Ig, and who needed intermittent infusions to maintain the improved condition.

Intravenous Ig treatment was not accompanied by serious side effects. None of the patients developed hepatitis. In 10 patients who had been treated at regular intervals for at least 2 years, human immunodeficiency virus antibodies could not be demonstrated.

One of the major advantages of treatment with intravenous Ig in comparison with prednisone is that improvement begins immediately. This is clearly demonstrated when we compare our results with that of a study in 60 patients[23] treated with 100 mg of prednisone daily for 2 to 4 weeks, followed by an alternate-day single dose of 100 mg until the clinical improvement reached a plateau phase. In that study the mean time for initial improvement was 1.9 months (mean time after treatment with intravenous Ig only 5 days), and the mean time to reach a clinical plateau was 6.6 months (after Ig only 5 weeks).

To maintain the improved condition,

40% of the patients needed intermittent intravenous Ig infusions every other week. We tried various schedules of reduction of the intravenous Ig dosage. We had more favorable results with tapering off the infusion dosage than with increasing the interval between the infusions. In nine of 21 patients, the dosage could be reduced to 0.25 g of intravenous Ig per kilogram of body weight every other week. Maintenance treatment with intravenous Ig is expensive. This treatment has to be compared with plasma exchange and to prednisone, which is the standard treatment in CIDP. There is no study that shows what the maintenance dosage of prednisone usually is and what the side effects are of long-term prednisone treatment in CIDP. It is reasonable to assume that the side effects of prednisone treatment in myasthenia gravis are not much different from CIDP. It has been estimated that approximately 25% of patients with myasthenia gravis develop serious side effects within 4 years of treatment with prednisone.[24] Prolonged plasma exchange has not been associated with any complications except anemia,[21] is about as expensive as intravenous Ig treatment, but is inconvenient for the patient.

Chronic inflammatory demyelinating polyneuropathy, according to the criteria outlined by Dyck et al,[15] is difficult to distinguish from some other neuropathies. The first neuropathy to consider has been described by McLeod et al.[20] This neuropathy is a slowly progressive axonal degeneration of undetermined cause. The characteristic history is that of a gradual onset of numbness, tingling, coldness, or burning sensation in the feet and hands, weakness of the legs, and, less commonly, weakness of the hands. Neurological examination may demonstrate distal muscle wasting and weakness in the lower limbs that may be quite pronounced. In McLeod and coworkers' series of patients, one third had areflexia of the legs, but total areflexia was less common. The cerebrospinal fluid protein level was often slightly elevated and the NCVs were slightly reduced and sometimes reached values that suggested a demyelinating neuropathy. If these patients are seen late in the course of the disease, distinction from CIDP may be difficult.

A second neuropathy that may be difficult to distinguish from CIDP is the nonsystemic vasculitic neuropathy.[21] The course in these patients may be stepwise progressive and thereafter static for a time. These patients may have severely affected legs and no or slight involvement of the arms.

Finally, CIDP may be confused with multifocal motor neuropathy. In the patients described by Pestronk et al,[22] asymmetrical weakness developed in one arm and progressed over 2 to 3 years to involve the other arm, legs, and trunk. High titers of antibodies to GM_1 ganglioside were demonstrated in these patients. These patients do not necessarily have areflexia of the arms or slowed NCV of the motor median nerve over the forearms. Initially, three of our patients had a similar course and in serum samples withdrawn at the beginning of the disease we could demonstrate high titers of antibodies to GM_1. These three patients did not respond to intravenous Ig.

We conclude that several factors that can be taken together as a progressive neuropathy of relatively short duration with clearly affected arms are associated with improvement after intravenous Ig treatment, and that the presence of these factors may have consequences for the choice of treatment in patients with CIDP.

Posttraumatic Torticollis

Daniel D. Truong, MD; Richard Dubinsky, MD; Neal Hermanowicz, MD;
Walter L. Olson, MD; Bruce Silverman, DO; William C. Koller, MD, PhD

• We report six cases of torticollis precipitated by neck trauma. The dystonia began 1 to 4 days after the trauma and differed clinically from idiopathic torticollis by marked limitation of range of motion, lack of improvement after sleep ("honeymoon period"), and absence of *geste antagonistique.* Worsening with action was not present; nor was there improvement with support as seen with idiopathic torticollis. Onset of pain immediately after the trauma and marked spasms of the paracervical muscles were other predominant features. Anticholinergic therapy was without benefit; however, some improvement occurred with botulinum toxin injection. It is concluded that torticollis can be caused by peripheral trauma and that it has unique clinical characteristics.

(*Arch Neurol.* 1991;48:221-223)

Torticollis is a focal dystonia characterized by twisting contraction of the neck muscles, resulting in forced turning of the head. An etiologic factor can rarely be identified for most cases of focal dystonia, although many secondary causes have been described.[1] Trauma, either to the basal ganglia structures[2] or peripherally to somatic regions, has been proposed as a cause of dystonia.[3,4] We report cases of torticollis that abruptly followed trauma to the neck, and describe the resultant clinical features.

REPORT OF CASES

Case 1.—A 39-year-old man was injured by a blow to the right side of his neck with a steel plate without injury to his head or loss of consciousness. He continued his work despite the severe pain in his neck, shoulder, and throat. On awakening the next morning, his head turned to the right. He was thought to have a whiplash injury producing a temporary "wryneck." However, the disorder persisted without improvement. For 6 months he received diazepam, which did not provide relief. Cervical roentgenograms, including odontoid views, were normal. A myelogram showed protruding disks at the C-4-C-5 and C-5-C-6 levels, and the patient underwent laminectomy and arthrodesis. The procedure, however, was without benefit. Subsequent trials of anticholinergic drugs and other medications were ineffective.

When examined 4 years after the accident, the patient presented the same features of torticollis that had developed the day after his injury. His chin turned to the right, with his head tilted to the left and shifted anteriorly; his left shoulder was elevated. Torticollis was present with or without head support; it worsened during standing and walking. The constant deviation of the patient's head did not allow movement past the midline, and he could not touch his right shoulder with his chin. There was severe pain in the region of the hypertrophic neck muscles that were involved in the turned neck posture (primarily, the right splenus capitis and the left sternocleidomastoid). The patient had not found any maneuvers or tricks to lessen the severity of the torticollis, nor was there relief when he rested his head against the wall. The neck posture returned to normal during sleep. On awakening each morning, he also reported a period of approximately 20 minutes when his torticollis was less severe.

The findings of the remainder of his neurologic examination were normal. Treatment with botulinum toxin led to marked improvement of neck posture, muscle hypertrophy, and pain.

Case 2.—A 47-year-old man was carrying a long 45-kg (100-lb) bar, when he lost his grip and tried to catch it with his right hand. He heard a "pop" and "crack" from the left side of his neck and shoulder and felt immediate pain in the upper part of his shoulder and the lateral aspect of his neck, with numbness throughout his left arm. The next day he awoke with his head pulling toward the right. The right splenius capitis, right upper trapezius, right sternocleidomastoid, and left scalene muscles contributed prominently to the pulling of his neck. He was unable to turn more than 30° to either the right or the left. He had not found any trick maneuvers to lessen the torticollis. His condition did not improve during sleep. His only other neurologic abnormality was a preexisting horizontal diplopia.

When the patient was seated, there was a tendency for his head to pull to the right, with his chin slightly elevated. Intermittently, there were tonic contractions lasting several seconds, which involved the left platysma, the right and left sternocleidomastoid, and the left trapezius muscles. Otherwise, the findings of the rest of his neurologic examination were normal. Cervical roentgenograms, including odontoid views; a computed tomographic (CT) scan of the head; and a cervical myelogram were normal. The patient was started on a course of trihexyphenidyl hydrochloride, without improvement. He declined further treatment.

Case 3.—A 27-year-old woman fell, striking her head and neck against the open door of a dishwasher. There was no loss of consciousness. The patient experienced immediate pain and muscle spasm. Her neck started to pull to the right within 2 days of the accident. Cervical roentgenograms and a CT scan of the patient's head and neck were normal. On examination 10 months

4/19/M	No	Immediate	1	No	Yes	En bloc	No	No	Normal	No	No
5/28/F	No	Immediate	4	No	No	En bloc	No	No	Normal	No	No
6/48/F	No	Immediate	1	No	No	En bloc	No	No	Stenosis at C-5-C-6 2 y later	No	Yes

*MRI indicates magnetic resonance imaging; CT, computed tomography; and RSD, reflex sympathetic dystrophy.

after the accident, she had pure laterocollis to the right, with her head tilted 40° from the midline and marked elevation of her right shoulder. She was unable to move her head out of this position by more than 10°. She turned en bloc. There was no "honeymoon period" in the morning. According to her mother, the condition persisted during sleep. The patient has not found any tricks that would alleviate her laterocollis. Electromyography showed continuous cocontraction of the right sternocleidomastoid, right scalenus medius, and right trapezius muscles. No cocontraction was noted in the corresponding left-sided muscles. Treatment with trihexyphenidyl and clonazepam was ineffective. Botulinum toxin injection into the above-mentioned muscles resulted in mild improvement.

Case 4.—At the age of 19 years, the patient ran into a partially opened garage door with enough force to knock himself 3 m (10 ft) backward. He "saw stars" but did not lose consciousness. He had neck pain immediately after the accident. That same day, he developed torticollis to the right, with his head tilted to the left. He did not have nausea, dizziness, or vomiting after the accident. Cervical spine roentgenograms, including odontoid views; skull roentgenograms and a pneumoencephalogram were normal. A CT scan of the head performed 35 years later was also normal. A multilevel posterior cervical rhizotomy performed in 1985 resulted in partial, temporary relief. The patient has not had any benefit from anticholinergic medications or clonazepam. Examination 38 years after the accident revealed torticollis with torsion to the right at 30°, tilting of the head to the left at 35 degrees, and moderately severe left shoulder elevation. Deviation occurred constantly. There were no trick movements that would alleviate the torticollis. His range of motion was limited to within 15° of the primary head position. He denied any honeymoon effect in the morning. He turned his body en bloc, with little mobility of the neck. According to his wife, his neck improved during sleep. Electromyographic studies revealed continuous cocontraction of the left sternocleidomastoid, left scalenus medius, left levator scapulae, left trapezius, left deep retrocollis, and bilateral splenus capiti muscles. Botulin injection into the above-mentioned muscles resulted in moderate improvement.

Case 5.—A 28-year-old woman was involved in two car accidents. In the first accident, her car was hit from the back as she was about to turn left. She heard a "snap" in her neck. She had the feeling of a stiff neck. At the emergency department, nothing was found in the cervical roentgenograms, and the patient was treated with cyclobenzaprine hydrochloride as well as a cervical collar. On the way home, her car struck the back of a van that pulled in front of her. She was seen again in the emergency department, and a second series of cervical roentgenograms did not demonstrate any abnormality. Because of her medication, the patient was drowsy for the first 3 days. On the fourth day, she noticed some pulling in the left side of her neck, and the previous stiffness increased. When examined by us, her neck was pulled fully to the left. She was unable to move her neck from this position. She would turn her body en bloc when she needed to turn to either side. She was not aware of any trick that would straighten her neck. She denied any honeymoon period in the morning. She also had pain in her left shoulder. Holding her head in a lateral position decreased her pain. Her laterocollis persisted during sleep. There was marked cocontraction of the left sternocleidomastoid and left scalenus medius muscles. Cervical spine roentgenograms, including odontoid views and those obtained during extension and flexion, odontoid view and CT scans of the spine did not reveal any abnormality. Botulinum toxin injection into the left sternocleidomastoid and scalenus medius muscles resulted in moderate improvement.

Case 6.—A 48-year-old woman developed torticollis after an accident in which she hit the top of her head against the roof of her car. Pain in her neck developed 1 day after the accident. This area became increasingly painful, and the patient had increasing difficulty in turning her neck from side to side. She did not have any tricks that would alleviate her torticollis. A bone scan, a magnetic resonance imaging scan, and a roentgenogram of the cervical spine obtained shortly after the accident were normal. Another magnetic resonance imaging scan performed 2 years later showed a stenosis at the C-5-C-6 level. The patient developed pain in her right arm; the pain started from the middle of the back of her head and radiated to the fourth and fifth fingers. She described a feeling of tingling, numbness, and coldness in her right hand. She felt coldness in her left foot. The findings of electromyography performed a few months after the accident were normal. The patient was hospitalized twice for excessive pain. A cervical myelogram obtained 1 year after the accident showed extensive degenerative arthritis throughout the neck and lumbar spine, with mild encroachment of the subarachnoid space and flattening of the spinal cord. Cervical CT showed narrowing of the anteroposterior diameter of the spinal canal at the C-5-C-6 level. The patient's medical history was remarkable for hypothyroidism and an L-4-L-5 disk operation 10 years previously. Neurologic examination revealed weakness of flexion and extension of the lower part of the left leg and the left ankle. The right shoulder, right arm, and left leg were cold and slightly cyanotic. Deep tendon reflexes were brisk bilaterally but more pronounced in the lower part of the left leg. Toes were down going. Pinprick sensation was decreased in the lower part of the left leg. Pronator drift was observed in the right arm. The patient's head tilted forward and to the left, and her chin was pointed to the right. Range of motion, which was decreased to 30° on each side, did not improve with lying down. The condition persisted during sleep. There was mild prominence of the right splenus capitis and left sternocleidomastoid muscles. The diagnosis of posttraumatic torticollis, cervical stenosis, and reflex sympathetic dystrophy was made. Anticholinergic medication had no benefit. However, treatment with botulinum toxin was helpful.

COMMENT

Suchowersky and Calne[5] described a case of torticollis following trauma to the neck. The patient involved developed torticollis 2 weeks after the initial event owing to atlantoaxial dislocation. None of our patients had subluxation as evidenced by cervical spine roentgenograms, including odontoid views, or by cervical CT. Brin et al[3] mentioned four patients with neck and shoulder injury who developed torticollis 12 hours to 8 weeks after the injury, and suggested that dystonia precipitated by peripheral injury may represent the clinical response to sensory perturbation on the extrapyramidal motor pathways via axonal sprouting. Jankovic and Van der Linden[6] described 17 patients with peripheral trauma prior to the onset of dystonia; one of them had torticollis. The preceding injuries occurred 1 day to 10 months before the onset of the dystonia. Sheehy and Marsden[7] noted that three cases in their series of 60 patients had a traumatic preceding event. They did not report the time relationship between the injuries and the occurrence of torticollis. In our patients, the torticollis began within 1 to 4 days of the traumatic events. The immediate onset of pain after the trauma and preceding the torticollis is of interest. Our cases did not reveal any pathology, despite intensive diagnostic studies. All patients were healthy prior to the incidents. Three patients heard cracking in their necks at the moment of the injuries. Furthermore, in contrast to previous reports, there was no history of familial neurologic disorders in our cases. In idiopathic torticollis, there is cocontraction of synergistic muscles, such as the sternocleidomastoid and the contralateral splenus capitis, resulting in twisting of the head. Patients with idiopathic torticollis are generally able to turn their heads easily in the same direction of the dystonic posture, although turning to the opposite side may be difficult. In our six cases, there was marked decrease in range of motion, and the patients were unable to turn their heads to either side. This relative fixation of the neck maybe a diagnostic clue for trauma-induced torticollis (Table). Although not reported by Suchowersky and Calne,[5] this fixation was also seen in their patient (O. Suchowersky, MD, oral communication, November 1989). This diagnostic clue, however, has also been seen by one of us (D.D.T.) in psychogenic torticollis. Psychogenic movement disorders often betray themselves through frequent change of symptoms, inconsistency over time, or incongruency with the classical dystonia.[8] In contrast, in our patients, the symptoms were unchanged and consistent over time. Another diagnostic clue is the report by four of our six patients that their torticollis persisted during sleep, in contrast to idiopathic torticollis, which often disappears. The clinical picture also differed from idiopathic torticollis in that a honeymoon period was not seen in our patients. Although this is not always present, patients with idiopathic torticollis frequently have a short episode of improvement each morning on awakening. The majority of our patients with trauma-induced torticollis did not improve with rest or support. But they also did not worsen with action, as is seen with idiopathic torticollis. The above-mentioned features may favor the classification of "nondystonic" torticollis in our patients. None of them responded to anticholinergics. Owing to the short follow-up of our cases (except cases 1 and 4), no statement can be made about remission. Jankovic and Van der Linden[6] analyzed 17 patients with dystonia occurring after trauma. Possible predisposing factors include exposure to neuroleptics, personal and family history of dystonia, essential tremor, prematurity, or developmental delay.[6] These predisposing factors were lacking in our cases, which may imply direct effect of the peripheral trauma. As with other acquired disorders, an aggressive search for cause should be initiated. In conclusion, the clinical picture of torticollis induced by peripheral trauma can be differentiated from its dystonic counterpart by the following features: decreased range of neck motions; persistence during sleep and head support; symptoms unchanged with action; and lack of family history, honeymoon period, and *geste antagonistique.*

The authors want to express their appreciation to Anne Young, MD, who referred two of the patients in this series to Dr Truong, and to Kathy Mistura, RN, and Karen Haglund for their dedicated assistance.

The Osler Institute

Neurology Boards Review Course

March 17-22, 1991 – Houston

April 11-13 – New Orleans October 24-26 – Philadelphia

Now, a special course for your written and oral board exams

OBJECTIVES:

- Increase basic knowledge and clinical skills in neurology
- Assist neurology residents to study efficiently
- Prepare board candidates to take board examinations
- Provide practicing neurologists with a review and update

METHODS:

- HOME STUDY MATERIALS with questions and answers based on previous examinations
- SEMINAR with projection slides and syllabus
- PRACTICE EXAMS with oral and written parts

*"The faculty was outstanding. The most pleasant thing was learning a tremendous amount, not only from world-famous authorities but from people who are relatively unknown as well."**

Part I Course: March 17-22 — Houston

Basic Sciences
- Neuroanatomy
- Neuropathology
- Neurochemistry
- Neurophysiology
- Neuropharmacology
- Neuroimmunology
- Neurogenetics

Clinical Sciences
- Neuroradiology
- Neuro-otology
- Neuro-ophthalmology
- Neuroendocrinology
- Neuroanesthesiology
- Alcohol & Substance Abuse
- Surgical Critical Care

Signs and Symptoms
- Headache and Pain
- Higher Cortical Function
- Movement Disorders
- Seizures and Epilepsy
- Delirium and Confusion
- Stupor and Coma
- Dementia and Alzheimer's

Neurologic Diseases
- Infectious Diseases
- Stroke & C.S.F. Disorders
- Tumors and Trauma
- Spinal Cord and Disc
- Demyelinative Diseases
- Multiple Sclerosis
- Metabolic & Toxic Diseases
- Nutritional Deficiency
- Parkinson's Disease
- Developmental Disorders
- Sleep Disorders

Neuromuscular and Child
- Neuropathies
- Myopathies
- Neuromuscular Junction
- Neonatal Neurology
- Pediatric Neurology

Optional Day
March 16 — Houston
- Skull Base Surgery
- Cerebropontine Angle
- Craniovascular Surgery
- Pituitary Surgery
- Spinal Surgery
- Neuroanesthesiology
- Surgical Critical Care

FACULTY

David Baskin, M.D.
Nachum Dafny, M.D.
Alden Dudley, M.D.
Richard George, M.D.
Hatem Megahed, M.D.
John S. Meyer, M.D.
Richard Moser, M.D.
Raj Narayan, M.D.
Tina Narayan, M.D.
Bernard Patten, M.D.
M. Nabil Rashad, M.D.
Gary Steinberg, M.D., Ph.D.
Rosa Tang, M.D.
Ronald Tintner, M.D.
Gage Van Horn III, M.D.

Part II Courses:

March 17-22 – Houston
April 11-13 – New Orleans
Oct. 24-26 – Philadelphia

The Part II Course is designed to prepare board candidates for their oral exam. The March 17-22, 1991 course in Houston will be for both written and oral exams. Lectures and mock oral exams will be held each day.

The three day course will be mock oral exams on differential diagnosis, treatment options, and complications. Following each exam the faculty will give a critique and answer questions.

Each participant will have an exam and critique session and observation of other sessions. Additional 25 minute sessions may be arranged for $70 and private sessions may be arranged for an additional $30. Past participants recommend both taking and observing mock oral exams.

*"Accommodations were comfortable...."**

COURSE AND LOCATION: The Part I Course consists of lectures and evening mock oral exams to help you prepare for your written and oral exams. The Part II Course is all mock oral exams for three days before and in the same city as each oral exam. Home study materials will be sent before the course. Past participants recommend taking the course well before written and oral exams and repeating for half price immediately before your exam. The March course will be at the Houston Marriot Medical Center Hotel, 6580 Fannin, Houston, Texas 77030.

*"...and those little extras...."**

LOWEST AIR FARES: Please call toll-free 1-800-548-8185 for group fares.

*"...the most education for the money."**

FEES AND COURSE HOURS:

• Surgeons or Residents	Surg.	Res.	Hrs.
• Part I Course (6 days)	$750	$500	60
repeating within 2 yrs.:	$375	$375	60
• Optional Day (March 16)	$150	$100	8
• Part II Course (3 days)	$540	$360	28
repeating within 2 yrs.:	$270	$270	28
• Extra mock oral exams:	$ 70	$ 70	1/2
• Private mock oral exams:	$100	$100	1/2

- **Add 10% within 10 days of the course.**
- Attendees not in course hotel add $20/day.
- A deposit of $50 will reserve your position.
- Home study materials will be mailed after half of the registration fee is received.

*"...home study material was extremely helpful."**

REFUNDS: Subject to a $50 fee, refunds will be made up until the seminar begins.

*"I feel it helped me pass the boards."**

Tegretol® 200 mg scored tablets
100 mg chewable tablets

carbamazepine USP

...because after seizure control, there's a lot of living to do!

TEGRETOL is indicated for children 6 years and older and adults.

Because of the potential for serious hematologic adverse reactions, it is important that you become thoroughly familiar with the full Prescribing Information for TEGRETOL on the next page, especially the boxed warning.

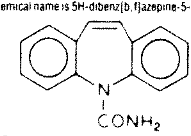
Chewable Tablets of 100 mg—red-speckled, pink   Tablets of 200 mg—pink

> WARNING
>
> APLASTIC ANEMIA AND AGRANULOCYTOSIS HAVE BEEN REPORTED IN ASSOCIATION WITH THE USE OF TEGRETOL. DATA FROM A POPULATION-BASED CASE CONTROL STUDY DEMONSTRATE THAT THE RISK OF DEVELOPING THESE REACTIONS IS 5-8 TIMES GREATER THAN IN THE GENERAL POPULATION. HOWEVER, THE OVERALL RISK OF THESE REACTIONS IN THE UNTREATED GENERAL POPULATION IS LOW, APPROXIMATELY SIX PATIENTS PER ONE MILLION POPULATION PER YEAR FOR AGRANULOCYTOSIS AND TWO PATIENTS PER ONE MILLION POPULATION PER YEAR FOR APLASTIC ANEMIA.
>
> ALTHOUGH REPORTS OF TRANSIENT OR PERSISTENT DECREASED PLATELET OR WHITE BLOOD CELL COUNTS ARE NOT UNCOMMON IN ASSOCIATION WITH THE USE OF TEGRETOL, DATA ARE NOT AVAILABLE TO ESTIMATE ACCURATELY THEIR INCIDENCE OR OUTCOME. HOWEVER, THE VAST MAJORITY OF THE CASES OF LEUKOPENIA HAVE NOT PROGRESSED TO THE MORE SERIOUS CONDITIONS OF APLASTIC ANEMIA OR AGRANULOCYTOSIS.
>
> BECAUSE OF THE VERY LOW INCIDENCE OF AGRANULOCYTOSIS AND APLASTIC ANEMIA, THE VAST MAJORITY OF MINOR HEMATOLOGIC CHANGES OBSERVED IN MONITORING OF PATIENTS ON TEGRETOL ARE UNLIKELY TO SIGNAL THE OCCURRENCE OF EITHER ABNORMALITY. NONETHELESS, COMPLETE PRETREATMENT HEMATOLOGICAL TESTING SHOULD BE OBTAINED AS A BASELINE. IF A PATIENT IN THE COURSE OF TREATMENT EXHIBITS LOW OR DECREASED WHITE BLOOD CELL OR PLATELET COUNTS, THE PATIENT SHOULD BE MONITORED CLOSELY. DISCONTINUATION OF THE DRUG SHOULD BE CONSIDERED IF ANY EVIDENCE OF SIGNIFICANT BONE MARROW DEPRESSION DEVELOPS.

Before prescribing Tegretol, the physician should be thoroughly familiar with the details of this prescribing information, particularly regarding use with other drugs, especially those which accentuate toxicity potential.

DESCRIPTION

Tegretol, carbamazepine USP, is an anticonvulsant and specific analgesic for trigeminal neuralgia, available as chewable tablets of 100 mg and tablets of 200 mg for oral administration. Its chemical name is 5H-dibenz[b,f]azepine-5-carboxamide, and its structural formula is



Carbamazepine USP is a white to off-white powder, practically insoluble in water and soluble in alcohol and in acetone. Its molecular weight is 236.27.

Inactive Ingredients. Colloidal silicon dioxide, FD&C Red No. 3 (chewable tablets only), FD&C Red No. 40 (200-mg tablets only), flavoring (chewable tablets only), gelatin, glycerin, magnesium stearate, sodium starch glycolate (chewable tablets only), starch, stearic acid, and sucrose (chewable tablets only).

CLINICAL PHARMACOLOGY

In controlled clinical trials, Tegretol has been shown to be effective in the treatment of psychomotor and grand mal seizures, as well as trigeminal neuralgia.

It has demonstrated anticonvulsant properties in rats and mice with electrically and chemically induced seizures. It appears to act by reducing polysynaptic responses and blocking the post-tetanic potentiation. Tegretol greatly reduces or abolishes pain induced by stimulation of the infraorbital nerve in cats and rats. It depresses thalamic potential and bulbar and polysynaptic reflexes, including the linguomandibular reflex in cats. Tegretol is chemically unrelated to other anticonvulsants or other drugs used to control the pain of trigeminal neuralgia. The mechanism of action remains unknown.

Tegretol tablets are adequately absorbed after oral administration at a slower rate than a solution, thus avoiding undesirably high peak concentrations. Tegretol chewable tablets may produce higher peak levels than the same dose given as regular tablets. Tegretol in blood is 76% bound to plasma proteins. Plasma levels of Tegretol are variable and may range from 0.5-25 μg/ml, with no apparent relationship to the daily intake of the drug. Usual adult therapeutic levels are between 4 and 12 μg/ml. Following oral administration, serum levels peak at 4 to 5 hours. The CSF/serum ratio is 0.22, similar to the 22% unbound Tegretol in serum. Because Tegretol may induce its own metabolism, the half-life is also variable. Initial half-life values range from 25-65 hours, with 12-17 hours on repeated doses. Tegretol is metabolized in the liver. After oral administration of 14C-carbamazepine, 72% of the administered radioactivity was found in the urine and 28% in the feces. This urinary radioactivity was composed largely of hydroxylated and conjugated metabolites, with only 3% of unchanged Tegretol. Transplacental passage of Tegretol is rapid (30 to 60 minutes), and the drug is accumulated in fetal tissues, with higher levels found in liver and kidney than in brain and lungs.

INDICATIONS AND USAGE

Epilepsy: Tegretol is indicated for use as an anticonvulsant drug. Evidence supporting efficacy of Tegretol as an anticonvulsant was derived from active drug-controlled studies that enrolled patients with the following seizure types:

1. Partial seizures with complex symptomatology (psychomotor, temporal lobe). Patients with these seizures appear to show greater improvement than those with other types.
2. Generalized tonic-clonic seizures (grand mal).
3. Mixed seizure patterns which include the above, or other partial or generalized seizures.

Absence seizures (petit mal) do not appear to be controlled by Tegretol (see PRECAUTIONS, General).

Trigeminal Neuralgia: Tegretol is indicated in the treatment of the pain associated with true trigeminal neuralgia.

Beneficial results have also been reported in glossopharyngeal neuralgia.

This drug is not a simple analgesic and should not be used for the relief of trivial aches or pains.

CONTRAINDICATIONS

Tegretol should not be used in patients with a history of previous bone marrow depression, hypersensitivity to the drug, or known sensitivity to any of the tricyclic compounds, such as amitriptyline, desipramine, imipramine, protriptyline, nortriptyline, etc. Likewise, on theoretical grounds its use with monoamine oxidase inhibitors is not recommended. Before administration of Tegretol, MAO inhibitors should be discontinued for a minimum of fourteen days, or longer if the clinical situation permits.

WARNINGS

Patients with a history of adverse hematologic reaction to any drug may be particularly at risk.

Severe dermatologic reactions including toxic epidermal necrolysis (Lyell's syndrome) and Stevens-Johnson syndrome, have been reported with Tegretol. These reactions have been extremely rare. However, a few fatalities have been reported.

Tegretol has shown mild anticholinergic activity; therefore, patients with increased intraocular pressure should be closely observed during therapy.

Because of the relationship of the drug to other tricyclic compounds, the possibility of activation of a latent psychosis and, in elderly patients, of confusion or agitation should be borne in mind.

PRECAUTIONS

General: Before initiating therapy, a detailed history and physical examination should be made.

Tegretol should be used with caution in patients with a mixed seizure disorder that includes atypical absence seizures, since in these patients Tegretol has been associated with increased frequency of generalized convulsions (see INDICATIONS AND USAGE).

Therapy should be prescribed only after critical benefit-to-risk appraisal in patients with a history of cardiac, hepatic or renal damage, adverse hematologic reaction to other drugs, or interrupted courses of therapy with Tegretol.

Information for Patients: Patients should be made aware of the early toxic signs and symptoms of a potential hematologic problem, such as fever, sore throat, ulcers in the mouth, easy bruising, petechial or purpuric hemorrhage, and should be advised to report to the physician immediately if any such signs or symptoms appear.

Since dizziness and drowsiness may occur, patients should be cautioned about the hazards of operating machinery or automobiles or engaging in other potentially dangerous tasks.

Laboratory Tests: Complete pretreatment blood counts, including platelets and possibly reticulocytes and serum iron, should be obtained as a baseline. If a patient in the course of treatment exhibits low or decreased white blood cell or platelet counts, the patient should be monitored closely. Discontinuation of the drug should be considered if any evidence of significant bone marrow depression develops.

Baseline and periodic evaluations of liver function, particularly in patients with a history of liver disease, must be performed during treatment with this drug since liver damage may occur. The drug should be discontinued immediately in cases of aggravated liver dysfunction or active liver disease.

Baseline and periodic eye examinations, including slit-lamp, funduscopy and tonometry, are recommended since many phenothiazines and related drugs have been shown to cause eye changes.

Baseline and periodic complete urinalysis and BUN determinations are recommended for patients treated with this agent because of observed renal dysfunction.

Monitoring of blood levels (see CLINICAL PHARMACOLOGY) has increased the efficacy and safety of anticonvulsants. This monitoring may be particularly useful in cases of dramatic increase in seizure frequency and for verification of compliance. In addition, measurement of drug serum levels may aid in determining the cause of toxicity when more than one medication is being used.

Thyroid function tests have been reported to show decreased values with Tegretol administered alone.

Hyponatremia has been reported in association with Tegretol use, either alone or in combination with other drugs.

Drug Interactions: The simultaneous administration of phenobarbital, phenytoin, or primidone, or a combination of two, produces a marked lowering of serum levels of Tegretol. The effect of valproic acid on Tegretol blood levels is not clearly established, although an increase in the ratio of active 10, 11-epoxide metabolite to parent compound is a consistent finding.

The half-lives of phenytoin, warfarin, doxycycline, and theophylline were significantly shortened when administered concurrently with Tegretol. Haloperidol and valproic acid serum levels may be reduced when these drugs are administered with Tegretol. The doses of these drugs may therefore have to be increased when Tegretol is added to the therapeutic regimen.

Concomitant administration of Tegretol with erythromycin, cimetidine, propoxyphene, isoniazid or calcium channel blockers has been reported to result in elevated plasma levels of carbamazepine resulting in toxicity in some cases. Also, concomitant administration of carbamazepine and lithium may increase the risk of neurotoxic side effects.

Alterations of thyroid function have been reported in combination therapy with other anticonvulsant medications.

Breakthrough bleeding has been reported among patients receiving concomitant oral contraceptives and their reliability may be adversely affected.

Carcinogenesis, Mutagenesis, Impairment of Fertility: Carbamazepine, when administered to Sprague-Dawley rats for two years in the diet at doses of 25, 75, and 250 mg/kg/day, resulted in a dose-related increase in the incidence of hepatocellular tumors in females and of benign interstitial cell adenomas in the testes of males.

Carbamazepine must, therefore, be considered to be carcinogenic in Sprague-Dawley rats. Bacterial and mammalian mutagenicity studies using carbamazepine produced negative results. The significance of these findings relative to the use of carbamazepine in humans is, at present, unknown.

Pregnancy Category C: Tegretol has been shown to have adverse effects in reproduction studies in rats when given orally in dosages 10-25 times the maximum human daily dosage of 1200 mg. In rat teratology studies, 2 of 135 offspring showed kinked ribs at 250 mg/kg and 4 of 119 offspring at 650 mg/kg showed other anomalies (cleft palate, 1; talipes, 1; anophthalmos, 2). In reproduction studies in rats, nursing offspring demonstrated a lack of weight gain and an unkempt appearance at a maternal dosage level of 200 mg/kg.

There are no adequate and well-controlled studies in pregnant women. Epidemiological data suggest that there may be an association between the use of carbamazepine during pregnancy and congenital malformations, including spina bifida. Tegretol should be used during pregnancy only if the potential benefit justifies the potential risk to the fetus.

Retrospective case reviews suggest that, compared with monotherapy, there may be a higher prevalence of teratogenic effects associated with the use of anticonvulsants in combination therapy. Therefore, monotherapy is recommended for pregnant women.

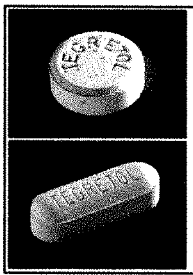
It is important to note that anticonvulsant drugs should not be discontinued in patients in whom the drug is administered to prevent major seizures because of the strong possibility of precipitating status epilepticus with attendant hypoxia and threat to life. In individual cases where the severity and frequency of the seizure disorder are such that removal of medication does not pose a serious threat to the patient, discontinuation of the drug may be considered prior to and during pregnancy, although it cannot be said with any confidence that even minor seizures do not pose some hazard to the developing embryo or fetus.

Labor and Delivery: The effect of Tegretol on human labor and delivery is unknown.

Nursing Mothers: During lactation, concentration of Tegretol in milk is approximately 60% of the maternal plasma concentration.

Because of the potential for serious adverse reactions in nursing infants from carbamazepine, a decision should be made whether to discontinue nursing or to discontinue the drug, taking into account the importance of the drug to the mother.

Pediatric Use: Safety and effectiveness in children below the age of 6 years have not been established.



Only TEGRETOL,
brand of carbamazepine,
provides the prescribing
flexibility of a 100-mg scored
chewable tablet, as well as
a 200-mg scored tablet.

ADVERSE REACTIONS

If adverse reactions are of such severity that the drug must be discontinued, the physician must be aware that abrupt discontinuation of any anticonvulsant drug in a responsive epileptic patient may lead to seizures or even status epilepticus with its life-threatening hazards.

The most severe adverse reactions have been observed in the hemopoietic system (see boxed WARNING), the skin and the cardiovascular system.

The most frequently observed adverse reactions, particularly during the initial phases of therapy, are dizziness, drowsiness, unsteadiness, nausea, and vomiting. To minimize the possibility of such reactions, therapy should be initiated at the low dosage recommended.

The following additional adverse reactions have been reported:

Hemopoietic System. Aplastic anemia, agranulocytosis, pancytopenia, bone marrow depression, thrombocytopenia, leukopenia, leukocytosis, eosinophilia, acute intermittent porphyria.

Skin. Pruritic and erythematous rashes, urticaria, toxic epidermal necrolysis (Lyell's syndrome) (see WARNINGS), Stevens-Johnson syndrome (see WARNINGS), photosensitivity reactions, alterations in skin pigmentation, exfoliative dermatitis, erythema multiforme and nodosum, purpura, aggravation of disseminated lupus erythematosus, alopecia, and diaphoresis. In certain cases, discontinuation of therapy may be necessary.

Cardiovascular System. Congestive heart failure, edema, aggravation of hypertension, hypotension, syncope and collapse, aggravation of coronary artery disease, arrhythmias and AV block, primary thrombophlebitis, recurrence of thrombophlebitis, and adenopathy or lymphadenopathy.

Some of these cardiovascular complications have resulted in fatalities. Myocardial infarction has been associated with other tricyclic compounds.

Liver. Abnormalities in liver function tests, cholestatic and hepatocellular jaundice, hepatitis.

Respiratory System. Pulmonary hypersensitivity characterized by fever, dyspnea, pneumonitis or pneumonia.

Genitourinary System. Urinary frequency, acute urinary retention, oliguria with elevated blood pressure, azotemia, renal failure, and impotence. Albuminuria, glycosuria, elevated BUN and microscopic deposits in the urine have also been reported.

Testicular atrophy occurred in rats receiving Tegretol orally from 4 to 52 weeks at dosage levels of 50 to 400 mg/kg/day. Additionally, rats receiving Tegretol in the diet for two years at dosage levels of 25, 75, and 250 mg/kg/day had a dose-related incidence of testicular atrophy and aspermatogenesis. In dogs, it produced a brownish discoloration, presumably a metabolite, in the urinary bladder at dosage levels of 50 mg/kg and higher. Relevance of these findings to humans is unknown.

Nervous System. Dizziness, drowsiness, disturbances of coordination, confusion, headache, fatigue, blurred vision, visual hallucinations, transient diplopia, oculomotor disturbances, nystagmus, speech disturbances, abnormal involuntary movements, peripheral neuritis and paresthesias, depression with agitation, talkativeness, tinnitus, and hyperacusis.

There have been reports of associated paralysis and other symptoms of cerebral arterial insufficiency, but the exact relationship of these reactions to the drug has not been established.

Digestive System. Nausea, vomiting, gastric distress and abdominal pain, diarrhea, constipation, anorexia, and dryness of the mouth and pharynx, including glossitis and stomatitis.

Eyes. Scattered, punctate, cortical lens opacities, as well as conjunctivitis have been reported. Although a direct causal relationship has not been established, many phenothiazines and related drugs have been shown to cause eye changes.

Musculoskeletal System. Aching joints and muscles, and leg cramps.

Metabolism. Fever and chills. Inappropriate antidiuretic hormone (ADH) secretion syndrome has been reported. Cases of frank water intoxication, with decreased serum sodium (hyponatremia) and confusion, have been reported in association with Tegretol use (see PRECAUTIONS, Laboratory Tests).

Other. Isolated cases of a lupus erythematosus-like syndrome have been reported. There have been occasional reports of elevated levels of cholesterol, HDL cholesterol and triglycerides in patients taking anticonvulsants.

A case of aseptic meningitis, accompanied by myoclonus and peripheral eosinophilia has been reported in a patient taking carbamazepine in combination with other medications. The patient was successfully dechallenged, and the meningitis reappeared upon rechallenge with carbamazepine.

DRUG ABUSE AND DEPENDENCE

No evidence of abuse potential has been associated with Tegretol, nor is there evidence of psychological or physical dependence in humans.

OVERDOSAGE

Acute Toxicity

Lowest known lethal dose: adults, >60 g (39-year-old man). Highest known doses survived: adults, 30 g (31-year-old woman); children, 10 g (6-year-old boy); small children, 5 g (3-year-old girl).

Oral LD50 in animals (mg/kg): mice, 1100-3750; rats, 3850-4025; rabbits, 1500-2680; guinea pigs, 920.

Signs and Symptoms

The first signs and symptoms appear after 1-3 hours. Neuromuscular disturbances are the most prominent. Cardiovascular disorders are generally milder, and severe cardiac complications occur only when very high doses (>60 g) have been ingested.

Respiration. Irregular breathing, respiratory depression.

Cardiovascular System. Tachycardia, hypotension or hypertension, shock, conduction disorders.

Nervous System and Muscles. Impairment of consciousness ranging in severity to deep coma. Convulsions, especially in small children. Motor restlessness, muscular twitching, tremor, athetoid movements, opisthotonos, ataxia, drowsiness, dizziness, mydriasis, nystagmus, adiadochokinesia, ballism, psychomotor disturbances, dysmetria. Initial hyperreflexia, followed by hyporeflexia.

Gastrointestinal Tract. Nausea, vomiting.

Kidneys and Bladder. Anuria or oliguria, urinary retention.

Laboratory Findings. Isolated instances of overdosage have included leukocytosis, reduced leukocyte count, glycosuria and acetonuria. EEG may show dysrhythmias.

Combined Poisoning. When alcohol, tricyclic antidepressants, barbiturates or hydantoins are taken at the same time, the signs and symptoms of acute poisoning with Tegretol may be aggravated or modified.

Treatment

The prognosis in cases of severe poisoning is critically dependent upon prompt elimination of the drug, which may be achieved by inducing vomiting, irrigating the stomach, and by taking appropriate steps to diminish absorption. If these measures cannot be implemented without risk on the spot, the patient should be transferred at once to a hospital, while ensuring that vital functions are safeguarded. There is no specific antidote.

Elimination of the Drug. Induction of vomiting.

Gastric lavage. Even when more than 4 hours have elapsed following ingestion of the drug, the stomach should be repeatedly irrigated, especially if the patient has also consumed alcohol.

Measures to Reduce Absorption. Activated charcoal, laxatives.

Measures to Accelerate Elimination. Forced diuresis.

Dialysis is indicated only in severe poisoning associated with renal failure. Replacement transfusion is indicated in severe poisoning in small children.

Respiratory Depression. Keep the airways free; resort, if necessary, to endotracheal intubation, artificial respiration, and administration of oxygen.

Hypotension, Shock. Keep the patient's legs raised and administer a plasma expander. If blood pressure fails to rise despite measures taken to increase plasma volume, use of vasoactive substances should be considered.

Convulsions. Diazepam or barbiturates.

Warning. Diazepam or barbiturates may aggravate respiratory depression (especially in children), hypotension, and coma. However, barbiturates should not be used if drugs that inhibit monoamine oxidase have also been taken by the patient either in overdosage or in recent therapy (within one week).

Surveillance. Respiration, cardiac function (ECG monitoring), blood pressure, body temperature, pupillary reflexes, and kidney and bladder function should be monitored for several days.

Treatment of Blood Count Abnormalities. If evidence of significant bone marrow depression develops, the following recommendations are suggested: (1) stop the drug, (2) perform daily CBC, platelet and reticulocyte counts, (3) do a bone marrow aspiration and trephine biopsy immediately and repeat with sufficient frequency to monitor recovery.

Special periodic studies might be helpful as follows: (1) white cell and platelet antibodies, (2) 59Fe—ferrokinetic studies, (3) peripheral blood cell typing, (4) cytogenetic studies on marrow and peripheral blood, (5) bone marrow culture studies for colony-forming units, (6) hemoglobin electrophoresis for A_2 and F hemoglobin, and (7) serum folic acid and B_{12} levels.

A fully developed aplastic anemia will require appropriate, intensive monitoring and therapy, for which specialized consultation should be sought.

DOSAGE AND ADMINISTRATION

Monitoring of blood levels has increased the efficacy and safety of anticonvulsants (see PRECAUTIONS, Laboratory Tests). Dosage should be adjusted to the needs of the individual patient. A low initial daily dosage with a gradual increase is advised. As soon as adequate control is achieved, the dosage may be reduced very gradually to the minimum effective level. Tablets should be taken with meals.

Epilepsy (see INDICATIONS AND USAGE)

Adults and children over 12 years of age—Initial: 200 mg b.i.d. Increase at weekly intervals by adding up to 200 mg per day using a t.i.d. or q.i.d. regimen until the best response is obtained. Dosage should generally not exceed 1000 mg daily in children 12 to 15 years of age, and 1200 mg daily in patients above 15 years of age. Doses up to 1600 mg daily have been used in adults in rare instances. ***Maintenance:*** Adjust dosage to the minimum effective level, usually 800-1200 mg daily.

Children 6-12 years of age—Initial: 100 mg b.i.d. Increase at weekly intervals by adding 100 mg per day using a t.i.d. or q.i.d. regimen until the best response is obtained. Dosage should generally not exceed 1000 mg. ***Maintenance:*** Adjust dosage to the minimum effective level, usually 400-800 mg daily.

Combination Therapy: Tegretol may be used alone or with other anticonvulsants. When added to existing anticonvulsant therapy, the drug should be added gradually while the other anticonvulsants are maintained or gradually decreased, except phenytoin, which may have to be increased (see PRECAUTIONS, Drug Interactions and Pregnancy Category C).

Trigeminal Neuralgia (see INDICATIONS AND USAGE)

Initial: 100 mg b.i.d. on the first day for a total daily dose of 200 mg. This daily dose may be increased by up to 200 mg a day using increments of 100 mg every 12 hours only as needed to achieve freedom from pain. Do not exceed 1200 mg daily.

Maintenance: Control of pain can be maintained in most patients with 400 mg to 800 mg daily. However, some patients may be maintained on as little as 200 mg daily, while others may require as much as 1200 mg daily. At least once every 3 months throughout the treatment period, attempts should be made to reduce the dose to the minimum effective level or even to discontinue the drug.

HOW SUPPLIED

Chewable Tablets 100 mg—round, red-speckled, pink, single-scored (imprinted Tegretol on one side and 52 twice on the scored side)

Bottles of 100	NDC 0028-0052-01
Unit Dose (blister pack)	
Box of 100	
(strips of 10)	NDC 0028-0052-61

Tablets 200 mg—capsule-shaped, pink, single-scored (imprinted Tegretol on one side and 27 twice on the scored side)

Bottles of 100	NDC 0028-0027-01
Bottles of 1000	NDC 0028-0027-10
Gy-Pak*—One Unit	
12 bottles—100 tablets each	NDC 0028-0027-65
Unit Dose (blister pack)	
Box of 100	
(strips of 10)	NDC 0028-0027-61

Samples, when available, are identified by the word *SAMPLE* appearing on each tablet.

Protect from moisture.

Dispense in tight container (USP).

Also available as: Tegretol suspension 100 mg/5 ml, in 450 ml bottles.

Printed in U.S.A.   C90-34 (Rev. 6/90)

Chemotherapy for Oligodendroglioma

Progress Report

J. Gregory Cairncross, MD, David R. Macdonald, MD

Six years ago, we began to notice that recurrent oligodendrogliomas, tumors that had regrown after one or more surgeries and radiotherapy, responded to chemotherapy. These tumors were clinically aggressive, contrast-enhancing, histologically anaplastic, and relatively pure. We concluded, after eight consecutive responses (see reference 1 for response criteria),[1] that anaplastic oligodendroglioma was a chemosensitive tumor.[2] In this article, we review our experience with chemotherapy for this uncommon brain tumor.

Table 1.—Summary of Treatment and Response: 'First' Recurrence*

Patient No.	Adjuvant Chemotherapy	Sites of Recurrence		Chemotherapy for "First" Recurrence	Response Assessment		Response Duration, mo
		Brain	Systemic		Brain	Systemic	
1	−	+	+	Carmustine	PR	CR	16
2	−	+	−	PCV	CR	. . .	18
3	Diaziquone	+	+	PCV	PR	CR	14
4	Carmustine	+	−	Diaziquone	PR	. . .	36
5	−	+	−	Fludarabine	PD	. . .	. . .
				PCV	PR	. . .	8
6	−	+	−	PCV	PR	. . .	13
7	−	+	−	PCV	PR	. . .	8
8	−	+	−	Diaziquone	PD	. . .	. . .
				PCV	PR	. . .	19
9	−	+	−	PCV	CR	. . .	34
10	Diaziquone	−	+	PCV	. . .	PR	8

*Prior surgery and radiotherapy. CR indicates complete response; PR, partial response; PD, progressive disease; minus sign, none or not applicable; plus sign, present; and PCV, a drug combination that includes procarbazine, lomustine (CCNU), and vincristine.

Table 1 summarizes the results of treatment for "first" recurrence. We have treated 10 patients, all have responded; two completely and eight partially. Patient 1 responded to carmustine (BCNU), patient 4 to diaziquone (AZQ), the others to a drug combination (PCV) that included procarbazine, lomustine (CCNU), and vincristine.[3] (Patient 5 failed to respond to fludarabine, patient 8 to diaziquone; both responded to PCV.) The median duration of response is 15 months (range, 8 to 36 months). All patients have relapsed (patients 5, 7, and 10 relapsed while receiving PCV; the others had late relapses). We think PCV (Table 2) is particularly effective chemotherapy for anaplastic oligodendroglioma, but other drugs or drug combinations may prove superior. Recently, Levin et al[4] reported that PCV is superior to carmustine in the treatment of newly diagnosed anaplastic glioma—a testament to its effectiveness for moderately aggressive glial tumors.

Patients with recurrent oligodendroglioma respond to chemotherapy, especially PCV, but are not cured. We have re-treated seven patients with "salvage" chemotherapy. Table 3 summarizes the results of treatment for second recurrence. Diaziquone and cisplatin were ineffective, but PCV and intravenous melphalan yielded partial responses. Patient 4 had a sustained partial response to PCV despite two prior chemotherapy programs; carmustine adjuvantly (ie, at diagnosis) and diaziquone at first recurrence. Experience with patient 4 indicates that some patients with recurrent oligodendroglioma will respond to a nitrosourea-based regimen (eg, PCV) even though treated previously with nitrosoureas. Extrapolating, some PCV responders may at relapse respond again to PCV. Inadequate bone marrow reserve precluded further chemotherapy for patient 4. Patients 7 and 8 had brief partial responses to intravenously administered melphalan. Inadequate bone marrow reserve limited our ability to give full doses, and may have compromised treatment.

In oncology, when an effective therapy for recurrent tumor is recognized, longer survival and some cures have followed aggressive treatment at diag-

§Continued response.

nosis. Encouraged by successful chemotherapy for recurrent oligodendroglioma, we have treated three newly diagnosed patients with PCV prior to radiotherapy and again observed responses; two complete and one partial (Table 4). These patients had residual or progressive tumor after initial surgery.[5] This approach to initial treatment is feasible and effective. It may or may not be superior to radiotherapy alone or other early treatment strategies. Intensive initial treatment seems logical, but we are proceeding cautiously because, for oligodendroglioma, there is concern that aggressive behavior cannot always be reliably predicted by histologic findings. Potentially toxic treatment may be inappropriate for indolent gliomas.[6]

Reports on small numbers of patients from single institutions may overestimate the effectiveness of "new" treatments. Accordingly, the National Cancer Institute of Canada's Clinical Trials Group is conducting a multicentered phase II study of "intensive PCV" for oligodendroglioma. Patients with measurable, newly diagnosed or recurrent, contrast-enhancing, relatively pure, anaplastic oligodendroglioma are eligible. This study will confirm, modify, or refute our findings and examine the pros and cons of a dose-escalated regimen.

The Central Nervous System Cancer Consortium, led by Schold, conducted a phase II study of intravenously administered melphalan for recurrent anaplastic glioma and observed that patients with oligodendroglioma were more likely to respond (55%) than those with nonoligodendroglioma (11%).[7] This important finding, and an interesting case report by Saarinen et al,[8] are further evidence that aggressive oligodendroglioma is a chemosensitive tumor. The Consortium has accrued additional patients with oligodendroglioma to this study and will report a definitive analysis of intravenously administered melphalan.

While documenting effective chemotherapy for recurrent oligodendroglioma, responses to chemotherapy prior to radiotherapy in new patients, and long survival compared with other malignant gliomas,[9] we observed systemic metastasis (patients 1, 3, 4, and 10 in this article, and three others[10]), hitherto considered a rare complication of oligodendroglioma. Moreover, we noticed changing patterns of spread in the 1980s. Multiple craniotomies followed by cervical lymph node metastasis characterized the early cases (eg, patient 1). Surgery, radiotherapy, and adjuvant chemotherapy followed by diffuse bony metastasis characterized the recent cases (eg, patients 3, 4, and 10). "Frequent" systemic metastasis may be related to longer survival and changing patterns of spread to aggressive initial treatment. Both can be interpreted as signs of progress in the treatment of anaplastic oligodendroglioma. After all, changing patterns of spread, including distant metastasis, were observed in ovarian cancer with the emergence of effective chemotherapy, aggressive multimodality treatment of the primary tumor, and longer survival.[11] Last, we speculate that metastasis occurred in patients 3 and 10 and perhaps in patient 4 because they received suboptimal early aggressive treatment (Table 1).

Two additional points deserve emphasis. First, we have no data to support the use of chemotherapy for indolent (ie, nonenlarging, nonenhancing, histologically "typical") oligodendroglioma, and second, it is our impression that anaplastic mixed gliomas (ie, oligoastrocytomas) are less sensitive to chemotherapy and have a poorer prognosis.[8]

Anaplastic gliomas are a heterogeneous group of tumors and may differ in their response to cytotoxic drugs. Chemotherapy has had little impact on glioblastoma multiforme, but we are increasingly convinced that anaplastic oligodendroglioma is a chemosensitive tumor. Currently, we are reexamining the predictive value of histologic findings, cautiously pursuing intensive initial treatment for newly diagnosed patients, and modifying our treatments for patients with recurrent oligodendroglioma.

The authors thank their colleagues in the Department of Clinical Neurological Sciences, Leslie Levin, MD, and S. Clifford Sebold, Jr, MD, for helpful discussions, and Pat Gray for preparing the manuscript.

Anaplastic Oligodendrogliomas

Terrence L. Cascino, MD

Over the past 30 years, tremendous effort has been put into discovering effective therapy for primary brain tumor. For the most part, these efforts have concentrated on high-grade gliomas. It has clearly been shown that these tumors are radiosensitive in some cases. There remains great pessimism, though, regarding these tumors, with many patients having little response to chemotherapy at the time of recurrence. This has spurred great interest in novel drugs and new methods of drug delivery to try to increase the effectiveness of chemotherapy.

Cairncross and Macdonald have made the observation that anaplastic oligodendrogliomas may be a subgroup of glioma, which, in fact, is highly chemosensitive. This is an extremely important observation for a number of reasons. If their observations are correct, neuro-oncologists can point to an example of a high-grade glioma whose course can be radically changed by the administration of chemotherapy. Hopefully, this will promote further interest in brain tumor treatments and less pessimism on the part of some physicians and patients. In addition, it is of interest that these dramatic responses were obtained using fairly conventional systemic chemotherapy rather than more toxic approaches.

An appropriate word of warning is voiced in this article, that further studies are needed to delineate the role of intensive PCV (procarbazine, lomustine, and vincristine) therapy in anaplastic oligodendroglioma. In addition, the role of chemotherapy in patients with newly diagnosed tumors must be explored further. Hopefully, the National Cancer Institute of Canada's clinical trial involving multiple centers for phase II study of the use of vincristine in anaplastic oligodendroglioma will further define the treatment of this tumor. In conclusion, Cairncross and Macdonald are to be congratulated for their pioneering work in oligodendroglioma. The results of their multicenter phase II study will be awaited with great anticipation.

Are Anaplastic Oligodendrogliomas Chemosensitive?

Conventional experience suggests that high-grade gliomas do not respond to chemotherapy. However, Cairncross and Macdonald have found anaplastic oligodendroglioma to be chemoresponsive. Their results are impressive, but their series is small. While questions remain about subtypes, dose, and the best chemotherapeutic combination, it is already clear that at least some anaplastic oligodendrogliomas are chemosensitive.—VLADIMIR HACHINSKI, MD, DSC (MED)

History of Neurology

An Early Description of Slowly Progressive Aphasia

Claudio Luzzatti, MD, Klaus Poeck, MD

• Slowly progressive aphasia without generalized dementia has become an important issue of present-day neuropsychological research. Historically, credit for the first description is usually given to Pick. Another German-speaking author who has published a vivid description of a pertinent case is Pick's contemporary, Max Rosenfeld. This author has also observed a patient with slowly progressive spatial disorientation and visual recognition deficit, and he has discussed these patients in a remarkably modern way in the context of partial atrophy of the brain.

(*Arch Neurol.* 1991;48:228-229)

Mesulam's seminal article on Slowly Progressive Aphasia Without Generalized Dementia[1] has stimulated the interest of researchers working in the field of degenerative cerebral disease. It was recognized that there exists similar cases presenting with progressive language disorder, but also with visual agnosia, spatial deficit, or apraxia.[2-4] The problem whether in the course of the disease process the patients develop other neuropsychological impairment evolving toward generalized dementia or whether the syndrome remains restricted to one cognitive domain is still controversial. Pathologic information is available only for very few cases, and is inconclusive. Therefore, at present, it is not possible to attribute these cases to one of the standard nosological entities of degenerative cerebral disease.

Historically, it is Pick[5-7] who deserves credit for publishing the first descriptions of slowly progressive circumscribed neuropsychological symptoms due to focal brain atrophy. We wish to draw attention to another author, Rosenfeld,[8] who has extensively discussed the problem of partial atrophy of the brain.

Max Rosenfeld was a German neurologist who studied medicine in Königsberg where, at this time, Lichtheim was professor of medicine. He continued his studies in Munich and Strasbourg (Alsace). He became associate professor at Strasbourg University in 1907, where he dedicated himself extensively to studies in the field of physiology and symptomatology of the cerebral hemispheres. Since 1920, he held the chair of Neurology and Psychiatry at Rostock University. Rosenfeld was a contemporary of Wernicke, Isserlin, Kleist, Bonnhoeffer, Alzheimer, Pick, and Goldstein. Yet he does not appear to have worked in close contact with these researchers. This makes the following shrewd clinical observations all the more remarkable.

In an article published in 1909[8] Rosenfeld presented two particularly well-described cases of "partial atrophy of the brain," which he followed up for several years. We report on his patient No. 1 who appears pertinent for the discussion of the status of slowly progressive aphasia.

At the age of 62 years, the patient sought medical advice at the hospital for Nervous Diseases of Strasbourg University. At that time he worked as an insurance agent. He complained of weakness of mentation and stated he had "forgotten about 1000 words." In spite of his complaints he still used to see people in his job. He also frequented coffee shops, played chess, and visited the theater. At times he tended to exhibit a somewhat bizarre behavior that was interpreted by Rosenfeld as indicating loss of intelligence. For instance, he submitted petitions to the local administration requesting that the name of a street be changed or a bridge be constructed.

The patient was well groomed and oriented to time and place. Memory for biographical events was intact, as were reading, spontaneous writing, and writing to dictation, copying, verbal comprehension, spontaneous speech, and repetition. He had no obvious memory problems and did not produce confabulations.

Rosenfeld noted a striking "verbal amnesia" for the names of objects. In a naming task the patient gave the correct name in only seven of about 30 items. In five instances he produced more or less appropriate circumlocutions, eg, glasses: I have had them fixed (showing his own glasses); match box: I always carry these to light something; water pipe: a hole where water comes out; and piece of string: to tie up something.

For four objects he could only indicate the material they are made of. In three instances he produced paraphasic misnamings, eg, pencil for brush; citadel for purse (but he added "I have it in my pocket"); and written document for pen. Naming was not facilitated by tactile or by auditory cuing. The kind of reaction was quite constant. Only rarely was he able to learn the names after repeated testing, eg, watch, matches, lamp, and brush. Rosenfeld noted that the patient remembered from one examination to the next which objects had been shown

to him before.

Asked to name fruits from memory he ventured only apples and "female apples" (pears). After some hesitation he added small peas, beans, and lentils. The only animal names he produced were dog and horse. Of birds he named only the swallow and called a canary "a small yellow singing bird from Africa, he is my friend."

Summing up, this patient presented with a marked language disorder of anomic type, whereas Rosenfeld did not note other obvious neuropsychological deficits.

Over the following 3 years the patient returned several times to the outpatient clinic, complaining of progressive loss of words. He never had a cardiovascular accident. On repeated examination he again was fully oriented. The prominent aspect was still the severe "verbal amnesia." His spontaneous speech appeared impoverished. Comprehension was intact. Reading and writing were not impaired, but he did not recognize orthographic errors in the text and could not remember the content of a written text. Memory for past events was incomplete with temporal mislocations. Digit span was reduced to four-digit numbers. He could describe pictures even with a latency of some minutes. However, he was unable to repeat short poems and stories or some isolated words. Calculation was still possible for addition, multiplication, and subtraction, but not for division.

One year later he was admitted to the hospital in physically poor shape. He died within a few days at age 66 years.

At autopsy there was no diffuse brain atrophy. However, there was striking atrophy of the left temporal lobe affecting the pole and the second and third temporal gyrus. In contrast, the first temporal gyrus was almost spared. The left sylvian fissure was enlarged. There was considerable reduction of the underlying white matter. The right temporal pole was only slightly atrophic. No ischemic, hemorrhagic, or inflammatory changes were noted on gross inspection or at the microscopic level. The number of glial cells or glial processes was not increased.

The most prominent finding within the atrophic gyri was the reduction of the number of neurons and nerve fibers. The structure of nerve fibers was not altered, neither within nor outside of the cells. The cortical cytoarchitecture was abolished. The number of nerve cells was extremely reduced. A well-preserved fibrillary structure was demonstrated in only a few cells and processes. Most neurons showed rather intact nuclei and perikarya filled with granular material. Many nerve cells were identified by their nucleus only that was surrounded by granular material (Pick bodies?, lipofuscin?, polyglucosan or Lewy bodies?—comment by the authors). The number of satellite cells was not increased. Osmium preparation did not show signs of presumably wallerian degeneration.

Rosenfeld considered this case as a further example of the degenerative "partial atrophy of the left temporal lobe" originally described by Pick.[5] He gave a succinct description of the clinical picture and the course of this disorder: After an initial stage characterized by slow decline of associative and judgment capacities (which might be termed abstract thinking in modern wording), the patients become conspicuous by a mild naming disorder evolving toward a marked amnesic aphasia with the prominent feature of a profound semantic-lexical disorder. Rosenfeld goes on to elaborate that these patients are unable to produce concrete nouns in a given context. At the same time the patients are able to read and repeat these same words even though they may not understand their meaning. In modern terms, they have a profound disruption of verbal semantics, whereas superficial operations are preserved. These symptoms do not occur as the sequelae of an "apoplectic insult" but rather in slow progression. The further course of the language disorder includes semantic paraphasias, comprehension deficit (*Worttaubheit*), and, finally, progressive breakdown of language functions. Rosenfeld also mentions that the patients may develop retrograde and anterograde memory deficit.

In the same article Rosenfeld described a patient with progressive spatial disorientation and visual recognition problems due to bilateral atrophy of the occipital lobe, in particular of the lingual gyrus. He discussed these and other cases[9] in the context of a progressive partial atrophy of the cerebral cortex.

Even though Rosenfeld's article gives a fine early description of a case presenting with slowly progressive aphasia, it does not address the crucial question of presence or absence of dementia in the final stage. The reason is that at the beginning of the century the notion of intelligence was not yet well defined, and embraced in the first place verbal skills that obviously were compromised in these patients. Mesulam[10] maintains that the absence of histologic features specific for Alzheimer's, Pick's, and Creutzfeldt-Jakob's disease is the pathoanatomic finding that permits distinguishing slowly progressive aphasia from other degenerative diseases. Obviously, the older authors did not yet recognize this problem.

Observations

Anterior Femoral Cutaneous Nerve Injury Following Femoral Artery Reconstructive Surgery

Jerry M. Belsh, MD

• Two cases are presented exhibiting symptoms and signs of bilateral anterior femoral cutaneous nerve injury, clinically sparing femoral nerve branches to the saphenous nerve and quadriceps muscles. This occurred following surgical dissection in the femoral triangles associated with femoral artery reconstructive surgery. Anterior femoral cutaneous nerve injury should be considered when anterior medial thigh pain and numbness occur following aortofemoral bypass graft surgery and other types of femoral artery reconstructive surgery.

(*Arch Neurol.* 1991;48:230-232)

Compressive mononeuropathies of the lower limbs related to surgical procedures are well known. They commonly involve the femoral, sciatic, and lateral femoral cutaneous nerves and, more distally, the tibial, peroneal, and saphenous nerves. We describe two cases of postsurgical sensory neuropathy that involved both anterior femoral cutaneous nerves (AFCNs) but clinically spared the rest of both femoral nerve trunks.

REPORT OF CASES

CASE 1.—A 48-year-old man presented with a 3-month history of aching and numbness in the anteromedial aspects of both thighs following bilateral femoral artery bypass graft surgery. Medical history included diabetes mellitus, chronic alcohol abuse, and two femoral artery reconstructive surgeries performed 3 and 4 years earlier. Neurological examination 6 months before the present surgery revealed a distal polyneuropathy without any evidence of femoral nerve dysfunction.

The present bypass surgery was prompted by progressive claudication and rest pain of the right leg and angiographic evidence of occlusion of the right limb of a previously implanted aortobifemoral graft. The procedure was a left-to-right femorofemoral crossover, connecting the left distal limb of the old aortobifemoral graft to the right deep femoral artery. The surgery was uneventful, although the operative report noted abundant scar tissue in the right side of the groin.

Five days after surgery the patient noted burning in both upper knees and an aching pain in both thighs anteromedially, followed a few days later by a dead, raw feeling in the same distribution. There was no difficulty walking, climbing stairs, or extending either knee. During the ensuing 3 months, burning around the knees and soreness-numbness of the anteromedial aspect of the thighs persisted. Symptoms increased with sitting or lying and were unaffected by walking.

Neurological examination 3 months after surgery revealed absent pin and cold sensation in a well-defined area of both thighs anteromedially, extending from 10 cm below the inguinal creases to just below both patellae (Figure, left). In addition, in the lower limbs there was a distal loss to pin, cold, and vibratory sensation bilaterally, although sensation was preserved in most of the saphenous nerve distribution. Strength and bulk of the lower limb muscles, including the quadriceps bilaterally, were normal. Deep tendon reflexes were brisk in both knees but absent in the ankles.

Standard motor and sensory nerve conduction studies (Table) were consistent with an axonal loss sensorimotor polyneuropathy. Motor conduction studies of both femoral nerves revealed normal latencies and amplitudes of the compound muscle action potentials. Needle electromyography (EMG) of both vastus medialis muscles was normal, with no signs of denervation or chronic neuropathy.

Carbamazepine was prescribed, with resultant improvement in the burning sensation. Neurological evaluation 1 year after surgery revealed patchy, less well-defined areas of diminished pin and cold sensation over both anteromedial thighs with some residual burning in those regions.

CASE 2.—A 72-year-old man presented with a 5-month history of medial right thigh pain and numbness following bilateral aortofemoral bypass surgery. Medical history included mild renal failure, rheumatoid arthritis of the knees, and recurrent leg phlebitis treated with oral warfarin sodium. During evaluation for the phlebitis, a computed tomographic scan revealed an aneurysm of the infrarenal abdominal aorta with extension into both common iliac arteries.

The aneurysm was surgically repaired with placement of bilateral aortofemoral bypass grafts. After surgery, the patient noticed a numb, dead sensation in the upper half of both thighs anteromedially, followed a week later by a persistent pain in the anterior right thigh. The numbness in the left leg improved considerably by 6 weeks after surgery. There were never any complaints of leg or thigh weakness. Computed tomography of the pelvis and abdomen 6 weeks after surgery showed no evidence of hematoma or mass lesion.

Neurological examination 5 months after surgery revealed decreased pin and cold sensation limited to an oval region involving both thighs anteromedially (right more than left), extending just below the inguinal ligament to about 10 cm above the knee (Figure, right). There was hyperesthesia over the anterior right thigh between the inguinal ligament and the knee. Strength and bulk of lower limb muscles, including the quadriceps bilaterally, were normal. Deep tendon reflexes were diminished in the right knee, normal in the left knee, and absent in both ankles.

Nerve conduction studies of the lower

*TL indicates terminal latency; Amp, amplitude; and CV, conduction velocity. There was no response in the right sural nerve for case 2.

†Stimulated at inguinal ligament, recorded at vastus medialis (distance, 28.5 cm, case 1; 30.0 cm, case 2).

limbs (Table) suggested a sensory polyneuropathy. Motor conduction studies of both femoral nerves revealed normal latencies and amplitudes. Needle EMG of the lower limbs revealed positive sharp waves at rest in the right vastus lateralis and an increase in long-duration polyphasic motor unit action potentials in the right vastus lateralis, right tibialis anterior, and right gastrocnemius muscles. Left and right vastus medialis and left vastus lateralis muscles were normal.

Follow-up examination 6 months after surgery showed complete resolution of the right anterior thigh pain with lessening of the bilateral sensory deficit in the thighs; 1 year after surgery, sensory and motor examination results of the lower limbs were normal.

COMMENT

Both patients suffered nerve injuries largely restricted to the AFCNs. The clinical syndrome of AFCN injury consists of numbness and aching pain in the thigh anteromedially, sometimes associated with a burning sensation in the knee, with no difficulty in walking or extending the knee. Cutaneous sensation is diminished or absent in the distribution of the AFCN but present in the distribution of the saphenous nerve, and motor examination, particularly of quadriceps strength, shows no abnormality. Both patients, in addition, had clinical and EMG evidence of a distal sensorimotor polyneuropathy, which may have made them more susceptible to isolated nerve injury. The subclinical neuropathic findings on right quadriceps EMG in case 2 suggest that, in this patient, mild injury to the right main femoral nerve trunk may have accompanied injury to the AFCN.

The anatomy of the femoral nerve and its AFCN branches may help to explain the precise localization of our patients' lesions. The femoral nerve, formed from the second, third, and fourth lumbar nerves, descends within the abdomen and passes behind the inguinal ligament into the thigh. In the proximal femoral triangle, the nerve divides into an anterior and a posterior division, both of which divide almost immediately into their respective branches.

The AFCN consists of cutaneous branches that arise from the anterior division of the femoral nerve. Lateral cutaneous branches of the AFCN (also known as the intermediate femoral cutaneous nerve) supply the anterior surface of the thigh as far distal as the knee, while medial cutaneous branches (also known as the medial femoral cutaneous nerve) supply the adjacent medial surface of the thigh.[1(pp759-762)-3] The anterior division of the femoral nerve also supplies muscular branches to the sartorius. The posterior division of the femoral nerve supplies the saphenous nerve and muscular branches to the quadriceps.

The most likely cause of the bilateral sensory mononeuropathy in our two patients was trauma from surgical dissection or retraction of the AFCN branches as they cross from a lateral to medial direction anterior to the common femoral artery bifurcation in the femoral triangle.[1(pp896-897),2] An alternative possibility is that trauma was limited to the anterior division of the femoral nerve in its position in the proximal femoral triangle, just lateral to the common femoral artery. Either possibility would explain the selective damage to AFCN branches while branches to the saphenous nerve and quadriceps muscles were clinically spared.

The clinical presentation of AFCN injury should not be confused with several other entities. Postoperative pain, burning, and numbness of the thigh in a patient with established peripheral vascular disease may suggest to the clinician a diagnosis of recurrent arterial vascular insufficiency, thrombophlebitis, or high lumbar (L-2 to L-4) radiculopathy. A careful neurological and medical evaluation, with particular attention to the cutaneous distribution of the AFCN, should help to clarify the diagnosis.

Isolated neuropathy of the AFCN without clinical involvement of the main femoral nerve trunk, although rarely reported[4,5] may not be an uncommon complication of peripheral vascular surgery. Based on our experience with two surgical cases, it seems that AFCN injury can have a relatively benign course with gradual resolution of symptoms and signs. Awareness of this entity, along with proper attention to meticulous surgical technique, may help prevent such a complication. In the setting of thigh pain and numbness following aortofemoral artery bypass and other femoral artery reconstructive surgery, AFCN injury should always be considered.

I wish to thank Sudhansu Chokroverty, MD, for reviewing the manuscript.

Frontal Impairment and Hypoperfusion in Neuroacanthocytosis

Florence Delecluse, MD; Jeanine Deleval, MS; Jean-Marie Gérard, MD;
Alex Michotte, MD; Diederik Zegers de Beyl, MD

• Cerebral blood flow tomography, by xenon 133 inhalation or HMPAO (^{99}mTc-*d*, *l*-hexamethyl-propylene amine oxime) technetium Tc 99m injection, revealed a severe hypoperfusion in both frontal lobes of a 40-year-old woman with confirmed neuroacanthocytosis. This finding occurred in conjunction with neuropsychological deficits consistent with selective frontal lobe dysfunction. This observation is the first documentation of this type of dementia in neuroacanthocytosis.

(*Arch Neurol.* 1991;48:232-234)

The differential diagnosis of vocal tics and choreic movements in the adult includes Huntington's disease, Gilles de la Tourette syndrome of late onset, and neuroacanthocytosis (NA).[1] Classically, acanthocytosis in the peripheral blood, an elevated creatine kinase level, and a normal lipoproteinemia concentration are characteristic of the NA syndrome.[2] Conversely, the neuroimaging findings in NA are described as similar to those of Huntington's disease, with caudate atrophy on computed tomographic scan and caudate hypometabolism[3,4] on positron emission tomography. We describe a case of a 40-year-old woman with NA (at first incorrectly diagnosed as Huntington's disease or late-onset Tourette syndrome) in whom single-photon emission tomography revealed a cerebral blood flow pattern of severe, isolated flow decrease in both frontal lobes, with little or no perfusional abnormalities in the caudate nuclei. Neuropsychological testing disclosed isolated frontal lobe dysfunction, a clinical pattern unlike those usually found in NA.[5,6]

REPORT OF A CASE

A 40-year-old woman, with no relevant personal or family history, was admitted for disabling abnormal and progressively worsening movements of 6 years' duration. The movements consisted of involuntary orofacial and tongue contractions with snorting, grunting, humming, lip smacking, and tongue clicks, as well as truncal dystonia and choreic movements of all four limbs. These involuntary movements were unrelieved by either benzodiazepines or tetrabenazine. Two years before admission, a progressive, hyperkinetic dysarthria began with the most salient speech dysfunctions being rate variability, irregular articulatory breakdown, hypernasality, occasional stuttering, and palilalia. One year before admission, generalized seizures developed, which responded to treatment with carbamazepine. There was no dysphagia, propulsive eating dystonia, or oral self mutilation.

Neuropsychological examination revealed a cooperative right-handed woman, well aware of her difficulties. There were no psychiatric manifestations and the Beck Depression Inventory proved that there was no concomitant depression. The patient's verbal and performance intelligence quotient scores were 102 and 75, values lower than expected given her level of academic achievement. The Wechsler memory scale revealed a lowered quotient at 86, with the patient's verbal learning capacity being superior to her nonverbal learning capacity. There was an inability to inhibit intrusion in interference conditions during the Stroop test (part C: colored color names, 69 seconds), as well as an inability to inhibit immediate response tendencies on the Alternating Sequence Test, and to achieve more than one category on the Wisconsin Card Sorting Test (20 perseverative errors, or 83%). She also had difficulties with "go-no-go" (excessive errors of commission on the no-go trials with both hands). Luria's numerical word problems could not be resolved though basic calculations were intact. Results of Rey's Auditory Verbal Learning Test were within normal limits. There were no word finding difficulties. Verbal fluency (names of animals and words beginning with P, F, and L in a one-minute time span) was preserved.

Cerebral computed tomographic scan showed a slight bilateral atrophy of the caudate nucleus (Fig 1). Nerve conduction velocities were normal, and electromyographic examination of the limbs disclosed no abnormalities. Microscopic examination of fresh serum revealed the presence of numerous acanthocytes (up to 30%), with a creatine kinase elevation and a normal lipoproteinemia concentration.

Quantified cerebral blood flow determination was performed by the xenon 133 inhalation method, and a rapidly rotating single-photon emission computed tomograph (Tomomatic 564 single-photon emission computed tomograph, Medimatic, Copenhagen, Denmark) developed by Lassen and Stokely. This method has been described in detail elsewhere.[7] Mean global cerebral blood flow and mean regional cerebral blood flow were calculated within six standardized paired regions of interest depicting the main vascular territories, as defined by Rootwelt and coworkers[8] (color

Reprint requests to Department of Neurology, Erasme Hospital, 808 route de Lennik, B-1070 Brussels, Belgium (Dr Delecluse).

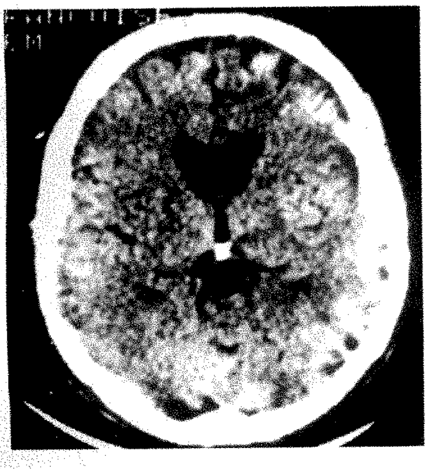

Fig 1.—The patient's cerebral computed tomographic scan showed a slight atrophy of the caudate nuclei.

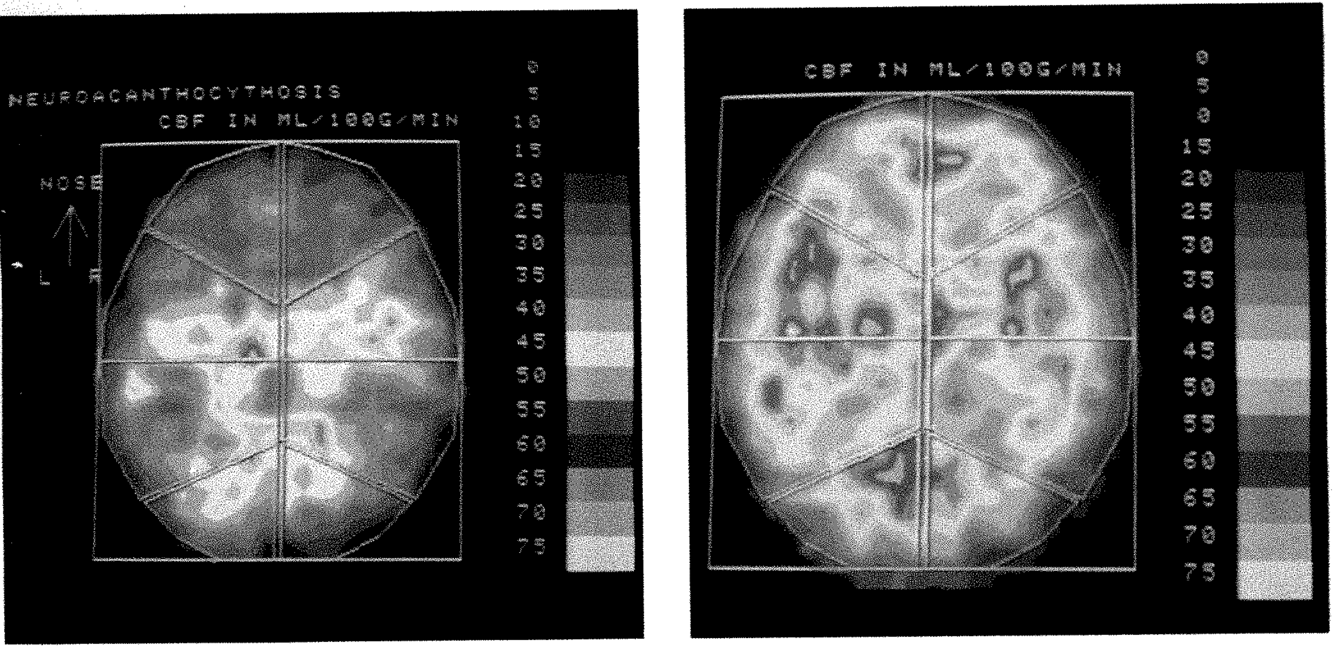
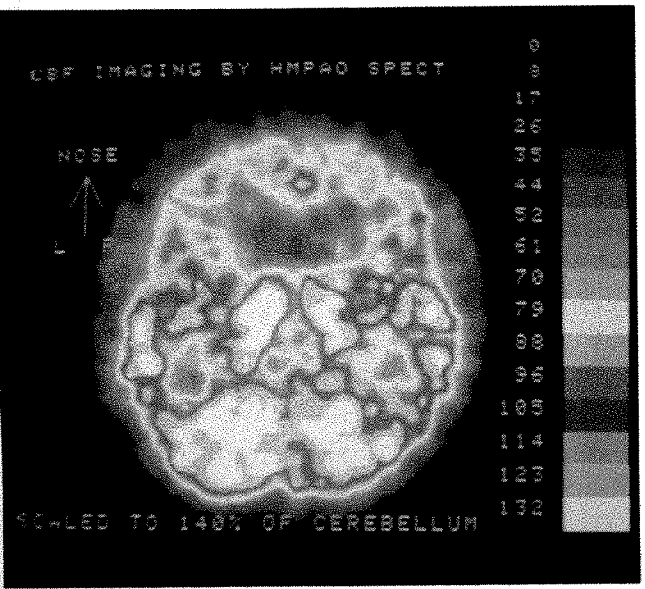
Mean Cerebral Blood Flow of the Patient and of 35 Control Subjects

Population	Age, y (Mean ± 1SD)	Global Cerebral Blood Flow mL/100 g per Minute (Mean ± 1 SEM)	Frontal Cerebral Blood Flow mL/100 g per Minute (Mean ± 1 SEM)
Present case	40.0	40.5	32.5
Control subjects (n = 35)	41.8 ± 2.2	50.9 ± 1.2	48.1 ± 1.1



Color Fig 1. Left, The patient's xenon 133 cerebral blood flow pattern, 5 cm above the orbitomeatal line showed a severe flow decrease in the frontal lobes. An arrow shows the slice orientation.

Right, The cerebral blood flow pattern of a normal control subject at the same level is included for comparison. At the extreme right of both flow maps is the cerebral blood flow scale, in milliliters per 100 g per minute, showing the identical scaling.



Color Fig 2.—The patient's HMPAO cerebral blood flow pattern, on the same slice as in color Fig 1, showing both the severe frontal hypoperfusion and the slight flow decrease in the caudate nuclei. The image is linearized according to Yonekura and coworker's technique,[9] and scaled to 140% of the cerebellum.

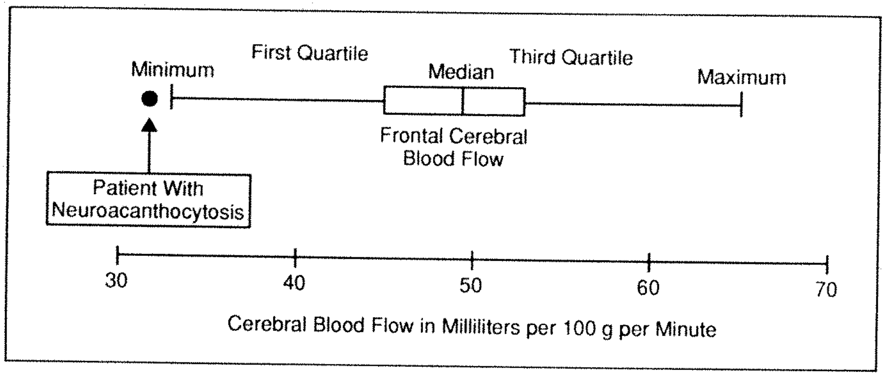


Fig 2.—A "box-and-whisker" plot of frontal flows in a normal population of 35 right-handed females. The patient's values are well outside the first percentile, as indicated by the arrow.

Fig 1), and applied to the third tomographic slice (located 5 cm above the orbitomeatal line). The quantitative xenon 133 cerebral blood flow measurements thus obtained in this case are depicted in the Table, compared with the same averaged results ± 1 SEM obtained in a control population of similar mean age, consisting of 35 normal, right-handed females. A "box-and-whisker plot" of the frontal flows (Fig 2) shows that our patient's frontal lobe values were well outside the normal range.

In order to better evaluate the flows in the caudate nuclei, another single-photon emission tomographic study was performed using the same equipment and a high-resolution collimator, after the intravenous administration of the new cerebral blood flow tracer HMPAO (^{99}mTc-*d,l*-hexamethylpropylene amine oxime). This tracer allows cerebral blood flow imaging of higher resolution than xenon 133, though absolute quantification is not routinely possible because of its long biological half-life. High-resolution cerebral blood flow imaging by HMPAO, using Yonekura[9] and Lassen's[7] "linearization technique," confirmed the existence of severe frontal hypoperfusion and revealed a slight decrease in the caudate nuclei (color Fig 2).

COMMENT

The neuropsychological pattern of NA has rarely been studied, and is still far from completely understood, as mental alterations are not usually a conspicuous feature of this disease.[5] When mental alterations do exist, the patterns so far described range from mild personality changes with slight intellectual impairment[10] to a "Huntington's disease-like" pattern with mild dementia, visuopraxic problems, anomia, and a retrieval deficit for verbal and nonverbal material.[6] Our observation adds another facet to the possible intellectual deficits in NA: that of predominantly frontal dysfunction, as witnessed by multiple perseverative errors, an excessive vulnerability to external intrusion, an inability to inhibit immediate but inappropriate responses, and an incapacity in initiating concepts.

These mental alterations were reflected in the perfusional abnormalities of this patient, a cerebral blood flow pattern quite different from that previously described in NA, Huntington's disease, or Tourette syndrome.[2-4] Both xenon 133 and HMPAO single-photon emission tomography revealed a severe focal flow decrease in both frontal lobes, with only a slight decrease in the caudate nuclei. Xenon 133 single-photon emission tomography also showed a slight global flow decrease. In contrast, the cerebral blood flow pattern in Huntington's disease is limited to a flow reduction in the caudate nuclei[4] while severe frontal lobe abnormalities are not seen in Tourette syndrome. This frontal lobe hypoperfusion is similar to that seen in the so-called "dementia of frontal lobe type," a clinical and cerebral blood flow entity, whose various pathogeneses include Pick's disease, Parkinson's disease, supranuclear palsy, and frontal lobe degeneration.[11,12] It is then ascribed to a specific degenerative process of the frontal lobes.[12] However, such a process has never been pathologically described in NA,[6] and the computed tomographic scan in this case showed no sign of frontal atrophy. Another possible cause of this frontal hypoperfusion would be a form of intrahemispheric diaschisis, similar to that described in the lesions of the thalamus[13] or the internal capsule,[14] and attributed to cortical deafferentation.[13]

Cerebral blood flow tomography would thus seem to be a very useful tool, not only in the differential diagnosis of diseases of the basal ganglia, such as Huntington's disease, Tourette syndrome, and neuroacanthocytosis, but also in the understanding of the physiological repercussions of the pathological processes involved.

Another day without migraine

Patients suffering two or more migraines per month, or especially severe migraine attacks, may need more than abortive therapy.

Prevention Abortive Agents Can't Provide

INDERAL® LA significantly reduces the frequency and severity of common-migraine headaches.

Effective, well-tolerated migraine prevention is usually achieved with 160 to 240 mg once daily.

INDERAL® LA. The only once-daily agent indicated for long-term migraine prevention.

Evaluate it for yourself.

ONCE-DAILY

INDERAL® LA

(PROPRANOLOL HCl)

LONG ACTING
CAPSULES
60, 80, 120, 160 mg

Stop migraine before it starts!

Protect Your Rx: Indicate
"Do Not Substitute"

Please see next page for brief summary of prescribing information.

INDERAL LA should not be used in the presence of congestive heart failure, sinus bradycardia, cardiogenic shock, heart block greater than first degree, and bronchial asthma.

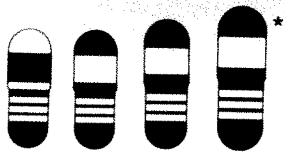
ONCE-DAILY

INDERAL® LA

(PROPRANOLOL HCl) LONG ACTING CAPSULES 60, 80, 120, 160 mg



Stop migraine before it starts!

BRIEF SUMMARY *(FOR FULL PRESCRIBING INFORMATION, SEE PACKAGE CIRCULAR.)*

INDERAL® LA brand of propranolol hydrochloride **(Long Acting Capsules)**

DESCRIPTION. INDERAL LA is formulated to provide a sustained release of propranolol hydrochloride. INDERAL LA is available as 60 mg, 80 mg, 120 mg, and 160 mg capsules.

CLINICAL PHARMACOLOGY. INDERAL is a nonselective, beta-adrenergic receptor-blocking agent possessing no other autonomic nervous system activity. It specifically competes with beta-adrenergic receptor-stimulating agents for available receptor sites. When access to beta-receptor sites is blocked by INDERAL, the chronotropic, inotropic, and vasodilator responses to beta-adrenergic stimulation are decreased proportionately.

INDERAL LA Capsules (60, 80, 120, and 160 mg) release propranolol HCl at a controlled and predictable rate. Peak blood levels following dosing with INDERAL LA occur at about 6 hours, and the apparent plasma half-life is about 10 hours. When measured at steady state over a 24-hour period the areas under the propranolol plasma concentration-time curve (AUCs) for the capsules are approximately 60% to 65% of the AUCs for a comparable divided daily dose of INDERAL Tablets. The lower AUCs for the capsules are due to greater hepatic metabolism of propranolol, resulting from the slower rate of absorption of propranolol. Over a twenty-four (24) hour period, blood levels are fairly constant for about twelve (12) hours, then decline exponentially.

INDERAL LA should not be considered a simple mg-for-mg substitute for conventional propranolol and the blood levels achieved do not match (are lower than) those of two to four times daily dosing with the same dose. When changing to INDERAL LA from conventional propranolol, a possible need for retitration upwards should be considered, especially to maintain effectiveness at the end of the dosing interval. In most clinical settings, however, such as hypertension or angina where there is little correlation between plasma levels and clinical effect, INDERAL LA has been therapeutically equivalent to the same mg dose of conventional INDERAL as assessed by 24-hour effects on blood pressure and on 24-hour exercise responses of heart rate, systolic pressure, and rate pressure product. INDERAL LA can provide effective beta blockade for a 24-hour period.

INDICATIONS AND USAGE. Hypertension: INDERAL LA is indicated in the management of hypertension; it may be used alone or used in combination with other antihypertensive agents, particularly a thiazide diuretic. INDERAL LA is not indicated in the management of hypertensive emergencies.

Angina Pectoris Due to Coronary Atherosclerosis: INDERAL LA is indicated for the long-term management of patients with angina pectoris.

Migraine: INDERAL LA is indicated for the prophylaxis of common migraine headache. The efficacy of propranolol in the treatment of a migraine attack that has started has not been established and propranolol is not indicated for such use.

Hypertrophic Subaortic Stenosis: INDERAL LA is useful in the management of hypertrophic subaortic stenosis, especially for treatment of exertional or other stress-induced angina,, palpitations, and syncope. INDERAL LA also improves exercise performance. The effectiveness of propranolol hydrochloride in this disease appears to be due to a reduction of the elevated outflow pressure gradient, which is exacerbated by beta-receptor stimulation. Clinical improvement may be temporary.

CONTRAINDICATIONS. INDERAL is contraindicated in 1) cardiogenic shock; 2) sinus bradycardia and greater than first-degree block; 3) bronchial asthma; 4) congestive heart failure (see WARNINGS), unless the failure is secondary to a tachyarrhythmia treatable with INDERAL.

WARNINGS. CARDIAC FAILURE: Sympathetic stimulation may be a vital component supporting circulatory function in patients with congestive heart failure, and its inhibition by beta blockade may precipitate more severe failure. Although beta blockers should be avoided in overt congestive heart failure, if necessary, they can be used with close follow-up in patients with a history of failure who are well compensated and are receiving digitalis and diuretics. Beta-adrenergic blocking agents do not abolish the inotropic action of digitalis on heart muscle.

IN PATIENTS WITHOUT A HISTORY OF HEART FAILURE, continued use of beta blockers can, in some cases, lead to cardiac failure. Therefore, at the first sign or symptom of heart failure, the patient should be digitalized and/or treated with diuretics, and the response observed closely, or INDERAL should be discontinued (gradually, if possible).

> IN PATIENTS WITH ANGINA PECTORIS, there have been reports of exacerbation of angina and, in some cases, myocardial infarction, following *abrupt* discontinuance of INDERAL therapy. Therefore, when discontinuance of INDERAL is planned, the dosage should be gradually reduced over at least a few weeks, and the patient should be cautioned against interruption or cessation of therapy without the physician's advice. If INDERAL therapy is interrupted and exacerbation of angina occurs, it usually is advisable to reinstitute INDERAL therapy and take other measures appropriate for the management of unstable angina pectoris. Since coronary artery disease may be unrecognized, it may be prudent to follow the above advice in patients considered at risk of having occult atherosclerotic heart disease who are given propranolol for other indications.

Nonallergic Bronchospasm (eg, chronic bronchitis, emphysema)—PATIENTS WITH BRONCHOSPASTIC DISEASES SHOULD IN GENERAL NOT RECEIVE BETA BLOCKERS. INDERAL should be administered with caution since it may block bronchodilation produced by endogenous and exogenous catecholamine stimulation of beta receptors.

MAJOR SURGERY: The necessity or desirability of withdrawal of beta-blocking therapy prior to major surgery is controversial. It should be noted, however, that the impaired ability of the heart to respond to reflex adrenergic stimuli may augment the risks of general anesthesia and surgical procedures.

INDERAL, like other beta blockers, is a competitive inhibitor of beta-receptor agonists and its effects can be reversed by administration of such agents, eg, dobutamine or isoproterenol. However, such patients may be subject to protracted severe hypotension. Difficulty in starting and maintaining the heartbeat has also been reported with beta blockers.

DIABETES AND HYPOGLYCEMIA: Beta blockers should be used with caution in diabetic patients if a beta-blocking agent is required. Beta blockers may mask tachycardia occurring with hypoglycemia, but other manifestations such as dizziness and sweating may not be significantly affected. Following insulin-induced hypoglycemia, propranolol may cause a delay in the recovery of blood glucose to normal levels.

THYROTOXICOSIS: Beta blockade may mask certain clinical signs of hyperthyroidism. Therefore, abrupt withdrawal of propranolol may be followed by an exacerbation of symptoms of hyperthyroidism, including thyroid storm. Propranolol may change thyroid-function tests, increasing T_4 and reverse T_3, and decreasing T_3.

IN PATIENTS WITH WOLFF-PARKINSON-WHITE SYNDROME, several cases have been reported in which, after propranolol, the tachycardia was replaced by a severe bradycardia requiring a demand pacemaker. In one case, this resulted after an initial dose of 5 mg propranolol.

PRECAUTIONS. GENERAL: Propranolol should be used with caution in patients with impaired hepatic or renal function. INDERAL is not indicated for the treatment of hypertensive emergencies.

Beta-adrenoreceptor blockade can cause reduction of intraocular pressure. Patients should be told that INDERAL may interfere with the glaucoma screening test. Withdrawal may lead to a return of increased intraocular pressure.

CLINICAL LABORATORY TESTS: Elevated blood urea levels in patients with severe heart disease, elevated serum transaminase, alkaline phosphatase, lactate dehydrogenase.

DRUG INTERACTIONS: Patients receiving catecholamine-depleting drugs such as reserpine should be closely observed if INDERAL (propranolol HCl) is administered. The added catecholamine-blocking action may produce an excessive reduction of resting sympathetic nervous activity which may result in hypotension, marked bradycardia, vertigo, syncopal attacks, or orthostatic hypotension.

Caution should be exercised when patients receiving a beta blocker are administered a calcium-channel-blocking drug, especially intravenous verapamil, for both agents may depress myocardial contractility or atrioventricular conduction. On rare occasions, the concomitant intravenous use of a beta blocker and verapamil has resulted in serious adverse reactions, especially in patients with severe cardiomyopathy, congestive heart failure or recent myocardial infarction.

Aluminum hydroxide gel greatly reduces intestinal absorption of propranolol.
Ethanol slows the rate of absorption of propranolol.
Phenytoin, phenobarbitone, and *rifampin* accelerate propranolol clearance.
Chlorpromazine, when used concomitantly with propranolol, results in increased plasma levels of both drugs.
Antipyrine and *lidocaine* have reduced clearance when used concomitantly with propranolol.
Thyroxine may result in a lower than expected T_3 concentration when used concomitantly with propranolol.
Cimetidine decreases the hepatic metabolism of propranolol, delaying elimination and increasing blood levels.
Theophylline clearance is reduced when used concomitantly with propranolol.

CARCINOGENESIS, MUTAGENESIS, IMPAIRMENT OF FERTILITY: Long-term studies in animals have been conducted to evaluate toxic effects and carcinogenic potential. In 18-month studies, in both rats and mice, employing doses up to 150 mg/kg/day, there was no evidence of significant drug-induced toxicity. There were no drug-related tumorigenic effects at any of the dosage levels. Reproductive studies in animals did not show any impairment of fertility that was attributable to the drug.

PREGNANCY: Pregnancy Category C: INDERAL has been shown to be embryotoxic in animal studies at doses about 10 times greater than the maximum recommended human dose.

There are no adequate and well-controlled studies in pregnant women. INDERAL should be used during pregnancy only if the potential benefit justifies the potential risk to the fetus.

NURSING MOTHERS: INDERAL is excreted in human milk. Caution should be exercised when INDERAL is administered to a nursing woman.

PEDIATRIC USE: Safety and effectiveness in children have not been established.

ADVERSE REACTIONS. Most adverse effects have been mild and transient and have rarely required the withdrawal of therapy.

Cardiovascular: Bradycardia; congestive heart failure; intensification of AV block; hypotension; paresthesia of hands; thrombocytopenic purpura; arterial insufficiency, usually of the Raynaud type.

Central Nervous System: Light-headedness; mental depression manifested by insomnia, lassitude, weakness, fatigue; reversible mental depression progressing to catatonia; visual disturbances; hallucinations; vivid dreams; an acute reversible syndrome characterized by disorientation for time and place, short-term memory loss, emotional lability, slightly clouded sensorium, and decreased performance on neuropsychometrics. For immediate formulations, fatigue, lethargy, and vivid dreams appear dose related.

Gastrointestinal: Nausea, vomiting, epigastric distress, abdominal cramping, diarrhea, constipation, mesenteric arterial thrombosis, ischemic colitis.

Allergic: Pharyngitis and agranulocytosis, erythematous rash, fever combined with aching and sore throat, laryngospasm, and respiratory distress.

Respiratory: Bronchospasm.

Hematologic: Agranulocytosis, nonthrombocytopenic purpura, thrombocytopenic purpura.

Auto-Immune: In extremely rare instances, systemic lupus erythematosus has been reported.

Miscellaneous: Alopecia, LE-like reactions, psoriasiform rashes, dry eyes, male impotence, and Peyronie's disease have been reported rarely. Oculomucocutaneous reactions involving the skin, serous membranes, and conjunctivae reported for a beta blocker (practolol) have not been associated with propranolol.

DOSAGE AND ADMINISTRATION: INDERAL LA provides propranolol hydrochloride in a sustained-release capsule for administration once daily. If patients are switched from INDERAL Tablets to INDERAL LA Capsules, care should be taken to assure that the desired therapeutic effect is maintained. INDERAL LA should not be considered a simple mg-for-mg substitute for INDERAL. INDERAL LA has different kinetics and produces lower blood levels. Retitration may be necessary, especially to maintain effectiveness at the end of the 24-hour dosing interval.

HYPERTENSION—*Dosage must be individualized.* The usual initial dosage is 80 mg INDERAL LA once daily, whether used alone or added to a diuretic. The dosage may be increased to 120 mg once daily or higher until adequate blood pressure control is achieved. The usual maintenance dosage is 120 to 160 mg once daily. In some instances a dosage of 640 mg may be required. The time needed for full hypertensive response to a given dosage is variable and may range from a few days to several weeks.

ANGINA PECTORIS—*Dosage must be individualized.* Starting with 80 mg INDERAL LA once daily, dosage should be gradually increased at three- to seven-day intervals until optimal response is obtained. Although individual patients may respond at any dosage level, the average optimal dosage appears to be 160 mg once daily. In angina pectoris, the value and safety of dosage exceeding 320 mg per day have not been established.

If treatment is to be discontinued, reduce dosage gradually over a period of a few weeks (see WARNINGS).

MIGRAINE—*Dosage must be individualized.* The initial oral dose is 80 mg INDERAL LA once daily. The usual effective dose range is 160-240 mg once daily. The dosage may be increased gradually to achieve optimal migraine prophylaxis. If a satisfactory response is not obtained within four to six weeks after reaching the maximal dose, INDERAL LA therapy should be discontinued. It may be advisable to withdraw the drug gradually over a period of several weeks.

HYPERTROPHIC SUBAORTIC STENOSIS—80-160 mg INDERAL LA once daily.

PEDIATRIC DOSAGE—At this time the data on the use of the drug in this age group are too limited to permit adequate directions for use.

Professional Opportunities

EXPANDING DYNAMIC neurology practice — BC/BE neurologist to join a busy, rapidly growing group neurology practice in Virginia suburbs of Washington, DC. Excellent opportunity for a compassionate, personable, hard working person to join our comprehensive neurodiagnostic team. Subspecialty training, especially EEG, evoked potentials, EMG, or sleep disorders preferred. Teaching and faculty appointments available. Send CV to: D. Hope, Neurology Center of Fairfax, Ltd., 3020 Hamaker Court, Fairfax, VA 22031.

METROPOLITAN WASHINGTON, DC AREA

Rapidly expanding neurology practice, with multiple locations, is seeking a BE/BC neurologist to join our dynamic team. Our offices are conveniently located, providing easy access to the areas finest hospitals as well as the nation's capital. We offer a competitive salary, excellent benefits and the opportunity for partnership. For more information please call or write:

William C. Nantz
10721 Main Street, Suite 2500
Fairfax, VA 22030 • (703) 352-5861

NEUROLOGIST: Excellent opportunity for board-certified/board-eligible neurologists to join two existing neurologists in a stimulating, busy practice. Marquette General Hospital is a 321-bed regional referral center, with a comprehensive neurophysiology department and state-of-the-art technology that includes magnetic resonance imaging and CT scanning, and a hospital-based family practice residency. Medical students from Michigan State University's College of Human Medicine are regularly assigned to the hospital and offer an opportunity for teaching. Marquette General Hospital and its medical staff are committed to building a center of excellence in the neurosciences and have the necessary financial resources. The development of these services will require the leadership and cooperation of physicians in the field of neurology, neurosurgery, psychiatry, physical medicine and rehabilitation. Salaried and private practice positions are available. If this special opportunity is of interest to you, please send CV to: Robert J. Raica, Marquette General Hospital, 420 West Magnetic Street, Marquette, MI 49855.

BC/BE NEUROLOGIST NEEDED — California. Excellent opportunity to establish your own private practice with no investment, guaranteed income. Strong referral base Proficiency in EEG/EMG required. Well equipped, 112-bed, full-service hospital. Our service area population is now 90,000; a growing area with new businesses and stable economy. Located in central California near Sequoia National Park, Tulare offers an excellent family-oriented lifestyle and all expected amenities. Beautiful homes close to hospital and office are affordably priced. Good schools, many community activities and abundant recreation including golf, tennis, mountain and equestrian activities. Easy access to all California's major metropolitan and resort areas. Please contact: Tulare District Hospital Physician Recruiting Office, P.O. Box 90112, Los Angeles, CA 90009. (800) 468-2687.

PLEASE NOTE—Address replies to box number ads as follows: Box number, ______, c/o AON, P.O. Box 1510, Clearwater, FL 34617.

Professional Opportunities

MAUI ORTHOPEDIC and Sports Medicine seeks neurologist to establish independent practice. Contact: William Gfeller, 450 Hookahi Street, Wailuku, Maui, HI 96793. (808) 244-5541.

NEUROLOGIST to join dynamic, midwest neurology group. This very busy practice is seeking an energetic neurologist with a strong interest in the clinical care of patients. This opportunity is located in a desirable, midwestern community abundant in cultural and sporting activities. The practice has a well-equipped radiology department with MRI and CT, and also, neurophysiology and neuropsychology departments. The appropriate candidate must be energetic, pleasant, BC/BE, with EMG experience. Please send curriculum vitae to: Box #814, c/o AON.

BC/BE NEUROLOGIST to join busy neurology practice in southeast Virginia, South Hampton Roads area, near Norfolk, Williamsburg and Outer Banks. University affiliation available. EMG and sleep training desirable. Competitive salary leading to partnership. Send CV to: Southeastern Neurology Group, Robert Hansen, MD, 1890 North Main Street, Suite G01, Suffolk, VA 23434.

CENTRAL OHIO—BC/BE neurologist to join busy solo practice located near Columbus. Experience in EMG, EEG and EP is desirable. Attractive compensation and benefits with productivity bonus. Full partnership in two years. Reply to: Robert M. Taylor, MD, 66 McMillen Drive, Newark, OH 43055. Or call: (614) 344-6992.

CHARLOTTE, NORTH CAROLINA: High quality group of six neurologists, all of whom are subspecialized, seeks to add a well-trained specialist. Contact: Mike Kaufman, MD, 126 Cottage Place, Charlotte, NC 28207. Or call: (704) 334-7311.

Neurologist

The Duluth Clinic, Ltd., a 160-physician, multi-specialty regional referral center in a metropolitan base of 125,000 with a regional referral base of 500,000 people, is seeking an additional board-certified/-eligible neurologist, preferably with interest in EMG and evoked potentials. Currently the staff includes one child neurologist, five adult neurologists and three neurosurgeons. State-of-the-art support services and equipment are in place. Ample outdoor recreational and cultural facilities are available. Please respond with complete curriculum vitae to:

James G. Brueggemann, MD
Medical Director

The Duluth Clinic, Ltd.
400 East Third Street, Duluth, MN 55805

An equal opportunity employer

BUCKS COUNTY, PENNSYLVANIA — Position available in this beautiful, southeastern Pennsylvania location for a BE/BC neurologist to join two young colleagues in a growing private practice. All diagnostic modalities locally available in this highly trained medical community, situated 30 minutes from Center City, Philadelphia and less than 90 minutes from Manhattan. High salary/benefits with potential for partnership. Reply: Box #807, c/o AON.

Professional Opportunities

FLORIDA'S CENTRAL EAST COAST—Adult neurologist with EMG training wanted to join group of eight neurologists. We live an a high tech, beachside community with great schools and affordable housing. Please send CV to: Search Committee, P.O. Box 693, Melbourne, FL 32902.

PEDIATRIC NEUROLOGY—Premier group in medium-sized community in the northern midwest seeking BC/BP pediatric neurologist to join two adult practitioners. Practice in place. Excellent financial package available leading to partnership. Phone or write: Mary Frances Lyons, MD, at (800) 678-7858 (local (314) 726-1603), c/o Cejka & Company, 222 South Central, Suite 400, St. Louis, MO 63105. FAX # (314) 726-0026.

— SOUTH FLORIDA —

BE/BC adult neurologist to join three young men in established suburban group between Miami and Fort Lauderdale. Busy office and multi-hospital practice. Good rewards for hard work. Excellent starting salary and benefits. Income growth and partnership to be offered to the right person. Immediate or July 1991 opening. Reply with CV to: Bay Harbor Neuro., 1135 Kane Concourse, Bay Harbor Islands, FL 33154. Or call Mrs. Sager: (305) 865-0063.

THIRD BC/BE NEUROLOGIST desired for growing neurology practice in southern Michigan. EMG/EEG expertise required. Wide referral base. Equipped neurophysiological laboratory available. Exceptional lifestyle and cultural resources. Attractive salary and incentives leading to partnership in one year. Please write to: Neill S. Hirst, MD, 250 West Eisenhower, Suite 100, Ann Arbor, MI 48103. Telephone: (313) 665-6638.

BE/BC NEUROLOGIST

To join an associate neurlogy practice in south-central Nebraska. This opportunity comes with the full support of your colleages and offers exceptional life style and practice potential. Income guarantee, relocation, MP, office paid. Send CV or contact: Armando L. Frezza, President, Medical Support Services, 8806 Balcones Club Drive, Austin, TX 78750. Office (800) 288-7420; FAX (512) 331-6741.

NEUROLOGIST WANTED, southern California: Opportunity for board-certified or -eligible adult neurologist to join a three-person group in an established practice in the northern San Diego, California, area. Position available as early as spring, 1991. Please reply with curriculum vitae to: Box #815, c/o AON.

PENNSYLVANIA LAUREL HIGHLANDS — Excellent opportunity for BE/BC private adult neurologist, 35 miles east of Pittsburgh, near skiing, etc. Partnership in neurology practice — hospital, private office, headache and sleep disorder center. Possible clinical appointment at Pitt Medical School. 1991 or 1992. Send CV to: James A. Rosen, MD, 900 Greengate North Plaza, Second Floor, Greensburg, PA 15601.

CLEVELAND CLINIC FLORIDA
NEUROLOGY

Cleveland Clinic Florida, a multi-specialty group practice, is seeking a BC/BE neurologist. Individual must have strong clinical skills, training and experience in EEG, evoked potentials, sleep physiology, and EMG, and be interested in helping develop new clinical programs/services in a rapidly growing department. Interest in clinical research and education a must. Excellent salary and benefit package. Send CV to:

Virgilio D. Salanga, MD
Department of Neurology
Cleveland Clinic Florida
3000 West Cypress Creek Road
Ft. Lauderdale, Florida 33309

CHICAGO SUBURBAN solo practitioner with a busy practice seeking a full-time BC/BE clinical neurologist. EMG skills required. Immediate opening. Wonderful opportunity to expand with possible early partnership. Reply with CV to: Yvonne Jurcik, MD, 125 East Lake Cook Road, Buffalo Grove, IL 60089.

Professional Opportunities

EXCELLENT OPPORTUNITY for BC/BE neurologist to join 80-physician, comprehensive, multispecialty group in San Francisco Bay Area. Large, varied referral base from pediatrics, IM, FP, and surgery. EMG/NCV, EEG, evoked response testing, CT, MRI, radiology support all available on site. Opportunity to interface with sepcialists of all types including neurosurgeons. Major university teaching affiliation encouraged and possible. Close proximity to 400-bed full service, modern hospital serving population of 300,000. Competitive guaranteed salary with bonus productivity plan for initial 18 months leading to partnership track. Extensive benefit package including housing incentives. Unique cultural, recreational and educational opportunities. Send CV to: Gary D. Zweig, MD, Recruitment Chairman, Sunnyvale Medical Clinic, P.O. Box 3496, Sunnyvale, CA 94088-3496.

The Ochsner Clinic in New Orleans is seeking a general neurologist to join the department. The individual should be board-certified or board-eligible in neurology.

The practice offers an opportunity to practice with physicians of superior training and ability in a setting that supports innovation and involvement in education. Teaching of neurology residents from Tulane University and medicine fellows from the Ochsner Clinic Medicine Department is an important part of the department's activity. Clinic research opportunities are available.

Please send curriculum vitae to:
Dr. Richard Strub
Chairman, Department of Neurology
Ochsner Clinic
1514 Jefferson Highway
New Orleans, LA 70121

NEUROLOGIST—NORTHERN CALIFORNIA: Develop an exceptional practice in conjunction with busy, established colleague who has clinical and research interests. Patient-oriented clinician will succeed and prosper. Located in the Bay area and close to the Monterey Peninsula. Option to enjoy a semi-rural lifestyle in a suburban area near the city and ocean. Financial package includes competitive salary plus generous incentive, full benefits, and paid overhead. Interviewing and relocation expenses are also paid. Send CV or call: Paul Byerlein, Jackson and Coker, Inc., 115 Perimeter Center Place, Suite 380 10074, Atlanta, GA 30346. Telephone: (800) 544-1987.

Positions Wanted

COMPHEALTH provides the finest locum tenens (temporary physician staffing) service nationwide. Each CompHealth neurologist is carefully screened and referenced ensuring you competent, reliable coverage. Have your practice covered or join us and cover other practices. Call CompHealth, the nation's oldest and largest supplier of temporary physician staffing services at: (800) 328-3043 toll-free; in Utah (801) 264-6400. Or write: 4021 South 700 East, Salt Lake City, UT 84107.

Fellowships

PAIN FELLOWSHIP. The Pain Service in the Department of Neurology at Memorial Sloan-Kettering Cancer Center is seeking a board-eligible/board-certified neurologist for a pain fellowship. This is a one- or two-year position that offers comprehensive training in pain evaluation and treatment, with a strong emphasis on cancer pain. Fellows will participate in clinical investigations of neuro-oncologic pain syndromes and the pharmacology of opioid analgesics. Laboratory research opportunities directed at the mechanisms of opiate action and the molecular pharmacology of opiate receptors are also available. Please contact: K.M. Foley, Department of Neurology, Memorial Sloan-Kettering Cancer Center, 1275 York Avenue, New York, NY 10021.

Southeast Coast
PEDIATRIC NEUROLOGIST

Excellent quality of life available in Savannah-Hilton Head area, site of the 1996 Olympic Games sailing events. Outstanding recreational opportunities, nation's largest urban historic district, and superb symphony are among the attractions of living here.

A well-trained, personable neurologist with special competence in child neurology is needed for a busy practice, currently consisting of two adult neurologists and one neurologist doing adult and child neurology, all with strong academic backgrounds. CT, EEG, EMG and physical therapy are available in-office with large hospital practice available in three hospitals, including a major regional teaching hospital, affiliated with the Medical College of Georgia. First year guarantee is $80,000 plus bonus, leading to full partnership after two years. Earnings potential, availability of strong multi-specialty support, and opportunities for teaching are extraordinary.

If interested contact:
Randy Wellman, Office Manager
Savannah
Neurological Associates, PC
P.O. Box 23059
Savannah, GA 31403 • (912) 354-8151

IMMEDIATE OPENING FOR A
GENERAL NEUROLOGIST

Private practice opportunity available immediately in east Tennessee with a well established neurologic practice.

Candidate should be BE/BC with competence in EEG, EMG and evoked potentials. Compensation individually negotiable. Excellent benefits also included. There is a wide variety of recreational facilities also available in the area.

Neurologist/ Clinical Neurophysiologist

with a special interest in evoked potentials. The individual would be expected to head the department's efforts in the fields of clinical evoked potentials, evoked potential monitoring in the operating room and neurointensive care units. The Cleveland Clinic Foundation is an equal opportunity employer.

Please send letter and current CV to:

Harold H. Morris, III, MD
Head, Section of Epilepsy &
Sleep Disorders
CLEVELAND CLINIC FOUNDATION
One Clinic Center - Mail Code M52
9500 Euclid Avenue
Cleveland, OH 44195
(216) 444-6236

The Department of Neurology, a rapidly expanding 26-member academic group practice with an accredited neurology residency training program at Henry Ford Hospital & Health Sciences Center, is seeking additional BC/BE neurologists with the following subspecialty interests:

(1) ambulatory neurology with a strong commitment to resident outpatient education
(2) neurorehabilitation
(3) clinical neurophysiology
(4) neuromuscular diseases
(5) movements disorders
(6) cerebrovascular diseases.

HFH & HSC is a tertiary care referral hospital with over 930 beds and is a teaching affiliate of the University of Michigan Medical Center. HFHS includes twenty-five health care sites including the main campus. Approximately 1/3 of the patients belong to largest HMO in Michigan. Staff engage in patient care, teaching and research activities. Excellent benefit package with competitive salaries, liberal vacation, conference and leave policies, and tax deferred retirement options. For further information contact:

K.M.A. Welch
Gossett Chair of Neurology
Department of Neurology
HENRY FORD HOSPITAL
2799 West Grand Boulevard
Detroit, MI 48202-2689
Telephone: (313) 876-3396
An equal opportunity employer.

Fellowships

FELLOWSHIP in Cerebrovascular Disease: Fellowships in cerebrovascular disease are available in the Department of Neurology at the University of Iowa. Comprehensive clinical training in management of patients with stroke is complemented by opportunities for clinical or basic research. Fellows are active participants in patient care and collaborate in several on-going local and multi-center clinical research studies. Candidates should be board-eligible or -certified in neurology and be licensed to practice medicine in the United States. Please send inquiries to either Harold P. Adams, Jr., MD, or Jose Biller, MD, Division of Cerebrovascular Diseases, Department of Neurology, University of Iowa, Iowa City, IA 52242. Or call: (319) 356-4110. The University of Iowa is an affirmative action/equal opportunity employer. Women, minorities and handicapped are encouraged to apply.

EPILEPSY FELLOWSHIP—Immediate opening available for one or two year epxerience. Active clinical program with emphasis on comprehensive medical and psychosocial management and clinical drug trials. Intermediate level epilepsy monitoring (video and ambulatory EEG) is in place. Training in EEG, EP, quantified EEG and brain mapping is available. Interested applicants may apply to: Dr. Venkat Ramani, Department of Neurology, Albany Medical College, Albany, NY 12208. (518) 445-5227.

Neuro-Ophthalmology Fellowship

The Departments of Ophthalmology and Neurology, University of Michigan. Position for one year period, July 7, 1992 to July 6, 1993. Trainee appointed as a lecturer with stipend and fringe benefits. Inquiries (before June 1, 1991) to: Jonathan D. Trobe, MD,

W K Kellogg Eye Center
1000 Wall Street, Ann Arbor, MI 48105
The University of Michigan
is an affirmative action employer.

EMG AND NEUROMUSCULAR Disease Fellowship, University of Mississippi Medical Center. Comprehensive fellowship in clinical neuromuscular disease, electromyography (including single fiber EMG), and muscle and nerve pathology for one or two years. The experience is based on a large MDA clinic (over 500 patients), an active EMG laboratory (700 procedures/year), and a muscle pathology laboratory within the department of neurology. Optional time in a basic science laboratory studying calcium and receptor mechanism in neuromuscular disease. Send CV and three letters of recommendation to: S.H. Subramony, MD, Department of Neurology, University of Mississippi Medical Center, 2500 North State Street, Jackson, MS 39216-4505. Equal opportunity employer, M/F/H/V.

GERIATRIC NEUROLOGY FELLOWSHIP. A two-year fellowship is available in geriatric neurology, beginning July 1, 1991. This VA-supported fellowship provides multi-disciplinary training in geriatric neurology with formal rotations on the 17-bed Geriatric Evaluation and Management Service at the Portland VA Medical Center. Fellows will also participate in clinical and research activities of the Alzheimer's Disease Center of Oregon and the Oregon Brain Aging Study at both the VA Medical Center and Oregon Health Sciences University. Emphasis will be placed on the design and implementation of independent research protocols. A broad range of research opportunities are available and include such topics a quantitative image analysis, the neuropharmacology of movement disorders, cerebrovascular disease in the elderly, and the neurology, neuropsychology and neuropathology of the very old. Applicants must be board-eligible or -certified in neurology. To apply, send CV and two letters of recommendation to: Jeffrey Kaye, MD, Director, Geriatric Neurology, Portland VA Medical Center, 3710 SW U.S. Veterans Hospital Road, P.O. Box 1034, Portland, OR 97207. Telephone: (503) 273-5171 or (503) 494-7772. The Department of Veterans Affairs and the Oregon Health Sciences University are equal opportunity employers.

PLEASE NOTE—Address replies to box number ads as follows: Box number, ________, c/o AON, P.O. Box 1510, Clearwater, FL 34617.

Fellowships

THE DEPARTMENT OF NEUROLOGY, University of Louisville has an opening for Clinical Neurophysiology Fellowship for 1991-92. Candidate will have the options to combine EEG with EMG or evoked potentials or clinical polysomnography. Interested applicants should forward their curriculum vitae to: Vasudeva Iyer, MD, Department of Neurology, University of Louisville, Louisville, KY 40292. (502) 588-7981.

NEURO-ONCOLOGY fellowship/instructorships are available for July 1991 and 1992. The University of California, San Francisco, Department of Neurological Surgery, Neuro-oncology Service, offers unprecedented opportunities to participate in chemotherapy and radiation therapy trials of children and adults with brain tumors. Practice is primarily outpatient; some 2,000 patient visits each year. An optional second year of laboratory research is available. Applicants for this position must possess a California medical license and be board-eligible or board-certified in neurology, neurosurgery, or medical oncology. There are two positions available. Apply to: Michael Prados, MD, University of California, Department of Neurological Surgery, Neuro-oncology Service, ACC-841, San Francisco, CA 94143-0372. The University of California is an equal opportunity/affirmative action employer. Women and minorities are encouraged to apply.

NEUROEPIDEMIOLOGY training fellowship available for board-eligible neurologist beginning July 1, 1991 at the Sergievsky Center and Neurological Institute, Columbia-Presbyterian Medical Center. Opportunity to earn a MS or MPH in epidemiology and work on ongoing clinical studies. Special interest in epilepsy or cerebrovascular disease preferred. Address inquiries to: Dr. W. Allen Hauser, Neuro-epidemiology Training Program, Sergievsky Center, 60 Haven Avenue, New York, NY 10032. Columbia University is an equal opportunity/affirmative action employer.

AGING AND DEMENTIA/BEHAVIORAL neurology clinical research fellowship available for board-eligible or -certified neurologist, July 1, 1991, at the Department of Neurology, Columbia Presbyterian Medical Center. Unexpected opening. Bi-lingual (Spanish) physician preferred. Address inquiries to: Dr. Richard Mayeux, Neurological Institute, 710 West 168th Street, New York, NY 10032. Columbia University is an equal opportunity employer.

Residencies

THE UNIVERSITY OF CHICAGO Neurology Department is offering a second year neurology residency position (PGY 3) beginning July 1991. For information contact: Richard P. Kraig, PhD, MD, Residency Director, Department of Neurology, University of Chicago Medical Center, 5841 South Maryland, BH - Box 425, Chicago, IL 60637. (312) 702-0151.

NEUROLOGY RESIDENCY PGY-2 position Stanford University — An unexpected neurology residency position is available starting July, 1991 at Stanford University Medical Center. For further information, contact: Dr. Gregory W. Albers, Director, Residency Training Program, Department of Neurology and Neurological Sciences, Stanford University Medical Center, Stanford, CA 94305. Equal opportunity employer.

CHILD NEUROLOGY RESIDENCY: The Department of Neurology at the Medical College of Wisconsin has a first year position available for July 1, 1991 in a fully accredited three year training program at the new Children's Hospital of Wisconsin. There are five full-time pediatric neurologists conducting a strong general clinical neurology program with programs of special emphasis in both clinical and basic science in oncology, epilepsy, neurobehavior and neuromuscular disorders. Candidates should have two years of pediatric training in a ACGME accredited program. Contact: Richard J. Konkol, MD, PhD, Chief of the Section of Pediatric Neurology at 8701 Watertown Plank Road, Milwaukee, WI 53226. (414) 266-4090 or Eric Maas, MD, Neurology Residency Director at Froedtert Memorial Lutheran Hospital, 9200 West Wisconsin Avenue, Milwaukee, WI 53226.

Faculty Positions

THE DEPARTMENT OF NEUROLOGY at the University of Louisville, School of Medicine is seeking a faculty member for a full-time academic appointment. Applicant must be board-eligible in neurology and neurodiagnostics, preferably with a completed fellowship in neurophysiology and electrodiagnostic medicine. Must be committed to education both at the undergraduate and graduate levels. Contact: William H. Olson, MD, Chairman, Department of Neurology, University of Louisville, Louisville, KY 40292. (502) 588-7981. EO/AAE.

THE UNIVERSITY OF MISSISIPPI Medical Center Department of Neurology invites applications for position of assistant professor from board-certified individuals with strong research, clinical and teaching skills. Persons with expertise in neuro-oncology, vascular disease and epilepsy are especially being sought. Please submit a letter of intent, curriculum vitae, and the names of three referring physicians to: Dr. James J. Corbett, Chairman, Department of Neurology, The University of Mississippi Medical Center, Jackson, MS 39216-4505. The University of Mississippi is an equal opportunity employer, M/F/H/V.

ACADEMIC NEUROLOGIST with board-eligibility in EMG sought by the Department of Neurology at The George Washington University Medical Center in Washington, DC. This non-tenure track, junior faculty position includes teaching responsibilities, patient care and the opportunity to develop a neuromuscular/EMG program. A competitive salary and excellent fringe benefits are provided. The George Washington University is an equal opportunity employer. Applications will be accepted until the position is filled. Please send inquiries and curriculum vitae to: Helene A. Emsellem, MD, Acting Chairman, Department of Neurology, 2150 Pennsylvania Avenue, NW, Suite 7-407, Washington, DC 20037.

ACADEMIC NEUROLOGIST with board-eligibility in clinical neurophysiology is sought by The Department of Neurology of The George Washington University Medical Center in Washington, DC. This tenure track position offers an opportunity to be involved in an active academic EEG/Sleep Laboratory and includes teaching and patient care activities. A competitive salary and excellent fringe benefits are provided. The George Washington University is an equal opportunity employer. Applications will be accepted until the position is filled. Please send inquiries and curriculum vitae to: Helene A. Emsellem, MD, Acting Chairman, Department of Neurology, 2150 Pennsylvania Avenue, NW, Suite 7-407, Washington, DC 20037.

LOYOLA UNIVERSITY Chicago Stritch School of Medicine, Department of Neurology invites applications for two positions at the assistant professor level. Applicants should be board-eligible or -certified in neurology and have subspecialty expertise in either epilepsy, movement disorders, cerebrovascular or neuromuscular diseases. Preference will be given to candidates with clinical research interests. Send CV to: Gastone Celesia, MD, Chairman, Neurology Department, Loyola University Chicago, 2160 South First Avenue, Chicago, IL 60153. Loyola University Chicago is an equal opportunity/affirmative action employer.

Medical Services

MRI/CT INTERPRETATIONS by board-certified radiologists via teleradiology or overnight mail. Teleradiology Associates, P.A., One University Place, Suite 350, Durham, NC 27707. (919) 419-1000.

MRI'S WANTED: If MRI interpretation is a problem for your group, Maine Independent Imaging can help. M.I.I. will perform overread or primary interpretation of your studies. Results faxed or phoned within 24 hours. We offer three very reasonable payment plans. For more information, call (207) 879-8278 or (207) 879-8250.

PLEASE NOTE—Address replies to box number ads as follows: Box number, ______, c/o AON, P.O. Box 1510, Clearwater, FL 34617.

Dilantin® Kapseals®
(extended phenytoin sodium capsules, USP)

Dilantin® KAPSEALS® (Extended Phenytoin Sodium Capsules, USP)

Before prescribing, please see full prescribing information. A Brief Summary follows.

INDICATIONS AND USAGE: Dilantin is indicated for the control of generalized tonic-clonic (grand mal) and complex partial (psychomotor, temporal lobe) seizures and prevention and treatment of seizures occurring during or following neurosurgery.

Phenytoin serum level determinations may be necessary for optimal dosage adjustments (see Dosage and Administration and Clinical Pharmacology).

CONTRAINDICATIONS: Phenytoin is contraindicated in those patients who are hypersensitive to phenytoin or other hydantoins.

WARNINGS: Abrupt withdrawal of phenytoin in epileptic patients may precipitate status epilepticus. When, in the judgment of the clinician, the need for dosage reduction, discontinuation, or substitution of alternative antiepileptic medication arises, this should be done gradually. However, in the event of an allergic or hypersensitivity reaction, rapid substitution of alternative therapy may be necessary. In this case, alternative therapy should be an antiepileptic drug not belonging to the hydantoin chemical class.

There have been a number of reports suggesting a relationship between phenytoin and the development of lymphadenopathy (local or generalized) including benign lymph node hyperplasia, pseudolymphoma, lymphoma, and Hodgkin's Disease. Although a cause and effect relationship has not been established, the occurrence of lymphadenopathy indicates the need to differentiate such a condition from other types of lymph node pathology. Lymph node involvement may occur with or without symptoms and signs resembling serum sickness, eg, fever, rash and liver involvement.

In all cases of lymphadenopathy, follow-up observation for an extended period is indicated and every effort should be made to achieve seizure control using alternative antiepileptic drugs.

Acute alcoholic intake may increase phenytoin serum levels while chronic alcoholic use may decrease serum levels.

In view of isolated reports associating phenytoin with exacerbation of porphyria, caution should be exercised in using this medication in patients suffering from this disease.

Usage in Pregnancy: A number of reports suggests an association between the use of antiepileptic drugs by women with epilepsy and a higher incidence of birth defects in children born to these women. Data are more extensive with respect to phenytoin and phenobarbital, but these are also the most commonly prescribed antiepileptic drugs; less systematic or anecdotal reports suggest a possible similar association with the use of all known antiepileptic drugs.

The reports suggesting a higher incidence of birth defects in children of drug-treated epileptic women cannot be regarded as adequate to prove a definite cause and effect relationship. There are intrinsic methodological problems in obtaining adequate data on drug teratogenicity in humans; genetic factors or the epileptic condition itself may be more important than drug therapy in leading to birth defects. The great majority of mothers on antiepileptic medication deliver normal infants. It is important to note that antiepileptic drugs should not be discontinued in patients in whom the drug is administered to prevent major seizures, because of the strong possibility of precipitating status epilepticus with attendant hypoxia and threat to life. In individual cases where the severity and frequency of the seizure disorder are such that the removal of medication does not pose a serious threat to the patient, discontinuation of the drug may be considered prior to and during pregnancy, although it cannot be said with any confidence that even minor seizures do not pose some hazard to the developing embryo or fetus. The prescribing physician will wish to weigh these considerations in treating or counseling epileptic women of childbearing potential.

In addition to the reports of increased incidence of congenital malformation, such as cleft lip/palate and heart malformations, in children of women receiving phenytoin and other antiepileptic drugs, there have more recently been reports of a fetal hydantoin syndrome. This consists of prenatal growth deficiency, microcephaly and mental deficiency in children born to mothers who have received phenytoin, barbiturates, alcohol, or trimethadione. However, these features are all interrelated and are frequently associated with intrauterine growth retardation from other causes.

There have been isolated reports of malignancies, including neuroblastoma, in children whose mothers received phenytoin during pregnancy.

An increase in seizure frequency during pregnancy occurs in a high proportion of patients, because of altered phenytoin absorption or metabolism. Periodic measurement of serum phenytoin levels is particularly valuable in the management of a pregnant epileptic patient as a guide to an appropriate adjustment of dosage. However, postpartum restoration of the original dosage will probably be indicated.

Neonatal coagulation defects have been reported within the first 24 hours in babies born to epileptic mothers receiving phenobarbital and/or phenytoin. Vitamin K has been shown to prevent or correct this defect and has been recommended to be given to the mother before delivery and to the neonate after birth.

PRECAUTIONS: General: The liver is the chief site of biotransformation of phenytoin; patients with impaired liver function, elderly patients, or those who are gravely ill may show early signs of toxicity.

A small percentage of individuals who have been treated with phenytoin has been shown to metabolize the drug slowly. Slow metabolism may be due to limited enzyme availability and lack of induction; it appears to be genetically determined.

Phenytoin should be discontinued if a skin rash appears (see "Warnings" section regarding drug discontinuation). If the rash is exfoliative, purpuric, or bullous or if lupus erythematosus, Stevens-Johnson syndrome, or toxic epidermal necrolysis is suspected, use of this drug should not be resumed and alternative therapy should be considered. (See Adverse Reactions.) If the rash is of a milder type (measles-like or scarlatiniform), therapy may be resumed after the rash has completely disappeared. If the rash recurs upon reinstitution of therapy, further phenytoin medication is contraindicated.

Phenytoin and other hydantoins are contraindicated in patients who have experienced phenytoin hypersensitivity. Additionally, caution should be exercised if using structurally similar (eg, barbiturates, succinimides, oxazolidinediones and other related compounds) in these same patients.

Hyperglycemia, resulting from the drug's inhibitory effects on insulin release, has been reported. Phenytoin may also raise the serum glucose level in diabetic patients.

Osteomalacia has been associated with phenytoin therapy and is considered to be due to phenytoin's interference with Vitamin D metabolism.

Phenytoin is not indicated for seizures due to hypoglycemic or other metabolic causes. Appropriate diagnostic procedures should be performed as indicated.

Phenytoin is not effective for absence (petit mal) seizures. If tonic-clonic (grand mal) and absence (petit mal) seizures are present, combined drug therapy is needed.

Serum levels of phenytoin sustained above the optimal range may produce confusional states
referred to as "delirium," "psychosis," or "encephalopathy," or rarely
dysfunction. Accordingly, at the first sign of acute toxicity, plasma levels ar
reduction of phenytoin therapy is indicated if plasma levels are excessiv
termination is recommended. (See Warnings.)

Information for Patients: Patients taking phenytoin should be advise
adhering strictly to the prescribed dosage regimen, and of informing the
condition in which it is not possible to take the drug orally as prescribe

Patients should also be cautioned on the use of other drugs or alcoholic
seeking the physician's advice.

Patients should be instructed to call their physician if skin rash devel

The importance of good dental hygiene should be stressed in
development of gingival hyperplasia and its complications.

Do not use capsules which are discolored.

Laboratory Tests: Phenytoin serum level determinations may be neces
dosage adjustments.

Drug Interactions: There are many drugs which may increase or decre
which phenytoin may affect. Serum level determinations for phenytoi
when possible drug interactions are suspected. The most commonly occ
are listed below: 1. Drugs which may increase phenytoin serum levels
intake, amiodarone, chloramphenicol, chlordiazepoxide, diazepam,
estrogens, H_2-antagonists, halothane, isoniazid, methylphenid
phenylbutazone, salicylates, succinimides, sulfonamides, tolbutamide

2. Drugs which may decrease phenytoin levels include: carbamazepine
reserpine, and sucralfate. Moban® brand of molindone hydrochloride
which interfere with the absorption of phenytoin. Ingestion times of
preparations containing calcium should be staggered in patients with low
to prevent absorption problems.

3. Drugs which may either increase or decrease phenytoin serum levels
sodium valproate, and valproic acid. Similarly, the effect of phenytoin on
acid, and sodium valproate serum levels is unpredictable.

4. Although not a true drug interaction, tricyclic antidepressants ma
susceptible patients and phenytoin dosage may need to be adjusted.

5. Drugs whose efficacy is
include: corticosteroids, cou
digitoxin, doxycycline, estro
contraceptives, quinidine, r
vitamin D.

Drug/Laboratory Test Intera
cause decreased serum levels
(PBI). It may also produce lowe
dexamethasone or metyrapon
cause increased serum levels c
phatase, and gamma glutamy

Carcinogenesis: See "Warnin
tion on carcinogenesis.

Pregnancy: See Warnings.

Nursing Mothers: Infant breast-feeding is not recommended for women
phenytoin appears to be secreted in low concentrations in human mil

ADVERSE REACTIONS: Central Nervous System: The most common ma
with phenytoin therapy are referable to this system and are usually dos
nystagmus, ataxia, slurred speech, decreased coordination and ment
insomnia, transient nervousness, motor twitchings, and headaches have a
have also been rare reports of phenytoin induced dyskinesias, including
and asterixis, similar to those induced by phenothiazine and other neur

A predominantly sensory peripheral polyneuropathy has been obser
long-term phenytoin therapy.

Gastrointestinal System: Nausea, vomiting, constipation, toxic hepa

Integumentary System: Dermatological manifestations sometimes ac
included scarlatiniform or morbilliform rashes. A morbilliform rash (n
common; other types of dermatitis are seen more rarely. Other more s
be fatal have included bullous, exfoliative or purpuric dermatitis, lupus e
Johnson syndrome, and toxic epidermal necrolysis (see Precautions)

Hemopoietic System: Hemopoietic complications, some fatal, have oc
in association with administration of phenytoin. These have included th
penia, granulocytopenia, agranulocytosis, and pancytopenia with or wi
pression. While macrocytosis and megaloblastic anemia have occurred,
respond to folic acid therapy. Lymphadenopathy including benign lymph
dolymphoma, lymphoma, and Hodgkin's Disease have been reported

Connective Tissue System: Coarsening of the facial features, enlarge
hyperplasia, hypertrichosis, and Peyronie's Disease.

Cardiovascular: Periarteritis nodosa.

Immunologic: Hypersensitivity syndrome (which may include, but is
such as arthralgias, eosinophilia, fever, liver dysfunction, lymphadeno
lupus erythematosus, immunoglobulin abnormalities.

OVERDOSAGE: The lethal dose in children is not known. The lethal do
to be 2 to 5 grams. The initial symptoms are nystagmus, ataxia, and dy
tremor, hyperreflexia, lethargy, slurred speech, nausea, vomiting. T
comatose and hypotensive. Death is due to respiratory and circulator

There are marked variations among individuals with respect to phen
toxicity may occur. Nystagmus, on lateral gaze, usually appears at
mcg/mL, dysarthria and lethargy appear when the plasma concentratio
as high a concentration as 50 mcg/mL has been reported without evid
as 25 times the therapeutic dose has been taken to result in a serum
mcg/mL with complete recovery.

Treatment: Treatment is nonspecific since there is no known antidote

The adequacy of the respiratory and circulatory systems should b
appropriate supportive measures employed. Hemodialysis can be co
is not completely bound to plasma proteins. Total exchange transfus
treatment of severe intoxication in children.

In acute overdosage the possibility of other CNS depressants, incl
borne in mind.

Caution – Federal law prohibits dispensing without prescription.

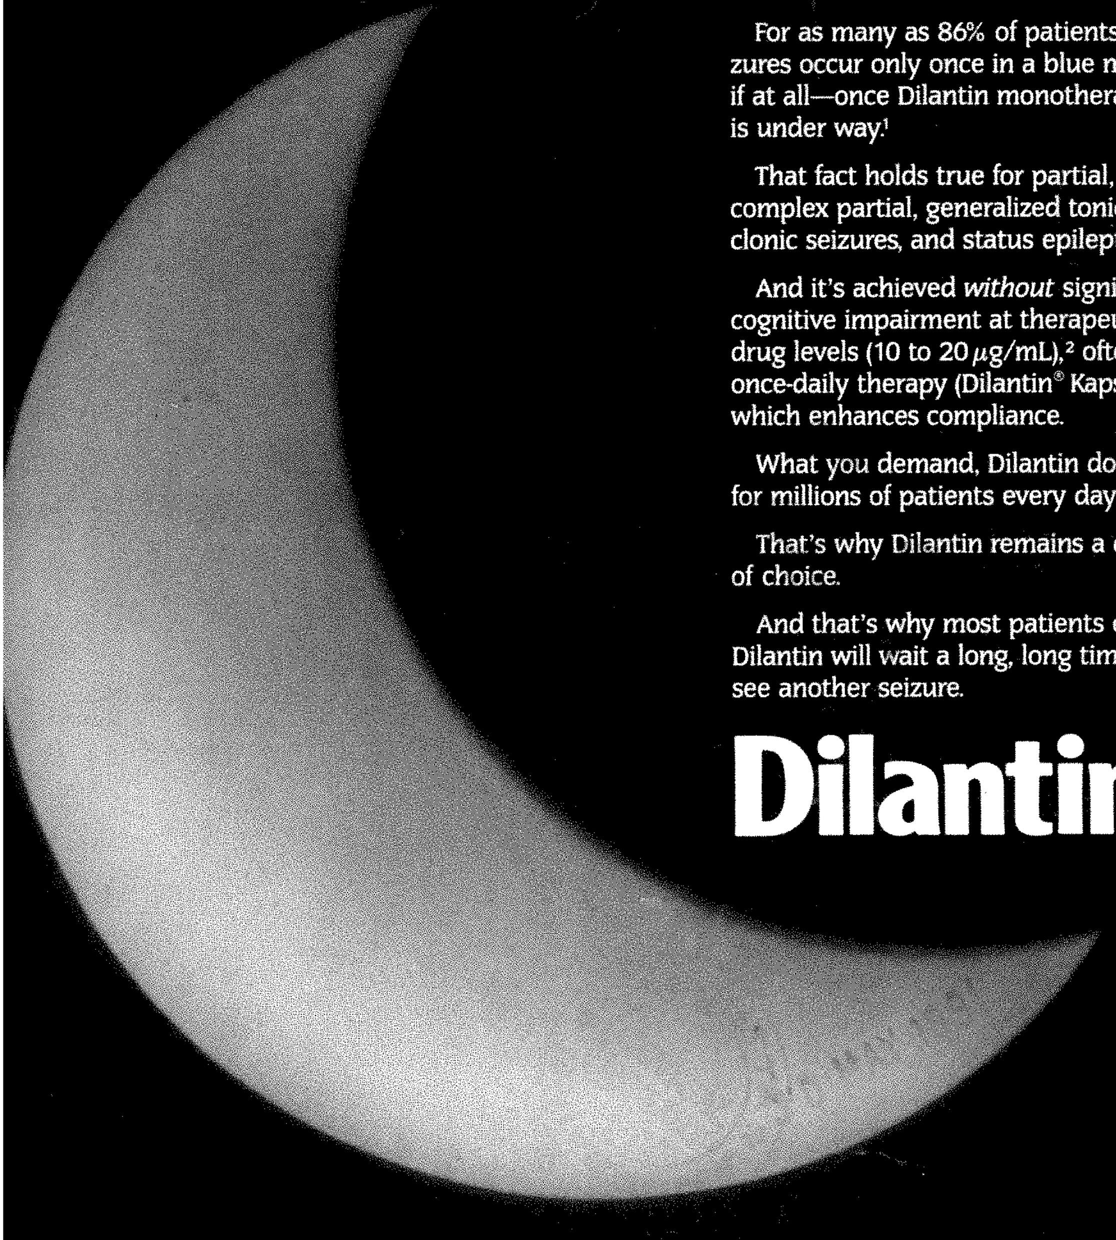
PI

As rare as a seizure on Dilantin® (extended phenytoin sodium capsules, USP) 100 mg



For as many as 86% of patients, seizures occur only once in a blue moon—if at all—once Dilantin monotherapy is under way.[1]

That fact holds true for partial, complex partial, generalized tonic-clonic seizures, and status epilepticus.

And it's achieved *without* significant cognitive impairment at therapeutic drug levels (10 to 20 μg/mL),[2] often *wit* once-daily therapy (Dilantin® Kapseals®), which enhances compliance.

What you demand, Dilantin does—for millions of patients every day.

That's why Dilantin remains a drug of choice.

And that's why most patients on Dilantin will wait a long, long time to see another seizure.

Dilantin®

Once in a blue moon" describes the phenomenon in which the moon appears as a brilliant blue. Seen worldwide following the volcanic eruption of Krakatoa in 1883, the blue moon occurs only when atmospheric cloud droplets, each less than 5 μm in diameter, form in abundance—an exceedingly rare event.[3]

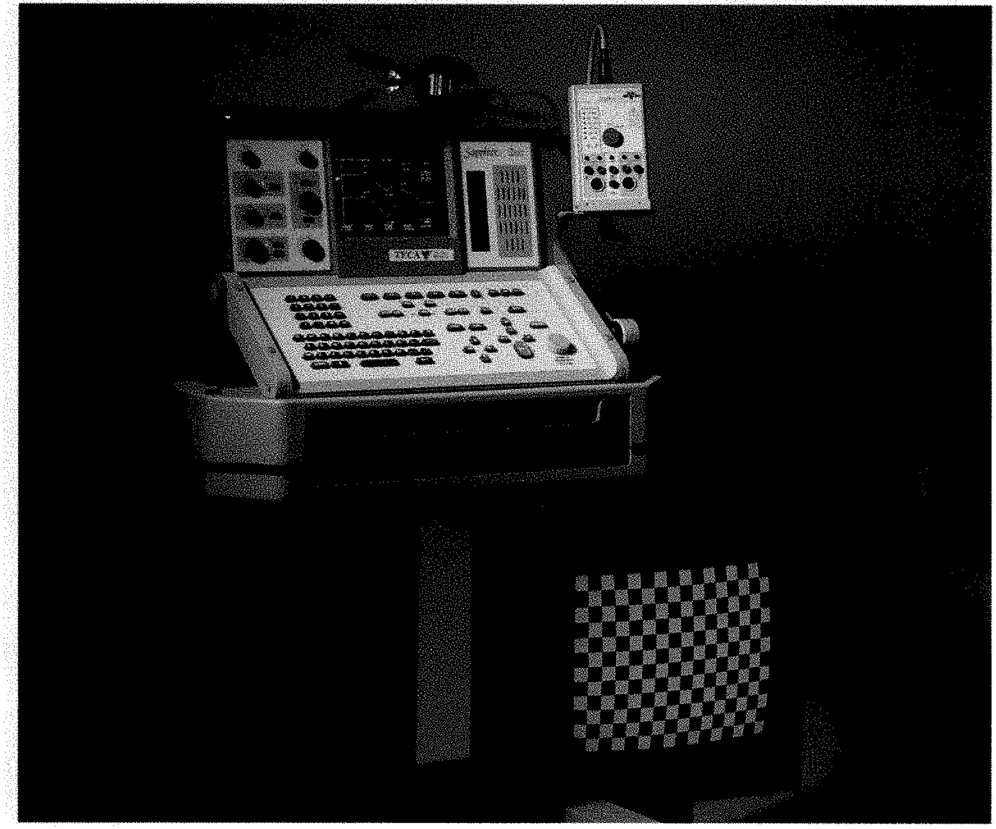
EMG/EP FOR THE 90'S FROM TECA



In the 90's two seemingly disparate terms – **advanced technology and affordability–** were linked when TECA announced the Sapphire line of portable EMG/EP instruments. Sapphire delivers all the advantages of modern technology with pricing that is realistic in today's economic environment.

- Superfast real-time EMG
- 1 or 2 channels
- EP stims
- Automatic NCV studies
- 10 seconds of EMG memory
- Trigger and delay line
- 16 programmable tests
- High resolution 12 bit A/D
- Trace annotation
- Disk drive and reporting
- Fast thermal printout

The Sapphire range is available from a single channel EMG instrument, to a full function EMG with Evoked Potentials. All routine tests are performed at the push of a button.

TECA Corporation, in the forefront with innovative instrumentation and a reputation for quality and service for over 40 years.

RE-INTRODUCE THE OLDEST ADVANCE IN MEDICINES.

It's called talking. If your older patients don't ask you about the prescriptions they've been given, make it a point to tell them what they need to know. Make sure they know the medicine's name, how and when to take it, precautions, and possible side effects. Encourage them to write down the information and ask you questions about things they don't understand.

You'll also want to take a complete medications history including both prescription *and* non-prescription medicines. The history can alert you to the potential for drug interactions and help you simplify their regimen.

Re-introduce the oldest advance in medicines. Make talking a crucial part of your practice. Because good, clear communication about medicines isn't a thing of the past. It's the way to a healthier future.

Before they take it, talk about it.

National Council on
Patient Information and Education.

INDERAL® LA (propranolol HCl) Long Acting Capsules
BRIEF SUMMARY OF PRESCRIBING INFORMATION:
CONSULT THE PACKAGE LITERATURE FOR FULL PRESCRIBING INFORMATION.

CONTRAINDICATIONS. INDERAL is contraindicated in 1) cardiogenic shock; 2) sinus bradycardia and greater than first-degree block; 3) bronchial asthma; 4) congestive heart failure (see WARNINGS), unless the failure is secondary to a tachyarrhythmia treatable with INDERAL.

WARNINGS. CARDIAC FAILURE: Sympathetic stimulation may be a vital component supporting circulatory function in patients with congestive heart failure, and its inhibition by beta-blockade may precipitate more severe failure. Although beta blockers should be avoided in overt congestive heart failure, if necessary, they can be used with close follow-up in patients with a history of failure who are well compensated and are receiving digitalis and diuretics. Beta-adrenergic blocking agents do not abolish the inotropic action of digitalis on heart muscle.

IN PATIENTS WITHOUT A HISTORY OF HEART FAILURE, continued use of beta blockers can, in some cases, lead to cardiac failure. Therefore, at the first sign or symptom of heart failure, the patient should be digitalized and/or treated with diuretics, and the response observed closely, or INDERAL should be discontinued (gradually, if possible).

IN PATIENTS WITH ANGINA PECTORIS, there have been reports of exacerbation of angina and, in some cases, myocardial infarction, following *abrupt* discontinuance of INDERAL therapy. Therefore, when discontinuance of INDERAL is planned, the dosage should be gradually reduced over at least a few weeks, and the patient should be cautioned against interruption or cessation of therapy without the physician's advice. If INDERAL therapy is interrupted and exacerbation of angina occurs, it usually is advisable to reinstitute INDERAL therapy and take other measures appropriate for the management of unstable angina pectoris. Since coronary artery disease may be unrecognized, it may be prudent to follow the above advice in patients considered at risk of having occult atherosclerotic heart disease who are given propranolol for other indications.

Nonallergic Bronchospasm (eg, chronic bronchitis, emphysema) – PATIENTS WITH BRONCHOSPASTIC DISEASES SHOULD IN GENERAL NOT RECEIVE BETA BLOCKERS. INDERAL should be administered with caution since it may block bronchodilation produced by endogenous and exogenous catecholamine stimulation of beta receptors.

MAJOR SURGERY: The necessity or desirability of withdrawal of beta-blocking therapy prior to major surgery is controversial. It should be noted that the impaired ability of the heart to respond to reflex adrenergic stimuli may augment the risks of general anesthesia and surgical procedures.

INDERAL, like other beta blockers, is a competitive inhibitor of beta-receptor agonists and its effects can be reversed by administration of such agents, eg, dobutamine or isoproterenol. However, such patients may be subject to protracted severe hypotension. Difficulty in starting and maintaining the heartbeat has also been reported with beta blockers.

DIABETES AND HYPOGLYCEMIA: Use beta blockers with caution in diabetic patients if a beta-blocking agent is required. Beta blockers may mask tachycardia occurring with hypoglycemia; other manifestations such as dizziness and sweating may not be significantly affected. Following insulin-induced hypoglycemia, propranolol may cause a delay in the recovery of blood glucose to normal levels.

THYROTOXICOSIS: Beta blockade may mask certain clinical signs of hyperthyroidism, thus abrupt withdrawal of propranolol may be followed by an exacerbation of symptoms of hyperthyroidism, including thyroid storm. Propranolol may change thyroid-function tests, increasing T_4 and reverse T_3, and decreasing T_3.

IN PATIENTS WITH WOLFF-PARKINSON-WHITE SYNDROME, several cases have been reported in which, after propranolol, tachycardia was replaced by severe bradycardia requiring a demand pacemaker. In one case this resulted after an initial dose of 5 mg propranolol.

PRECAUTIONS. GENERAL: Use with caution in patients with impaired hepatic or renal function. INDERAL is not indicated for the treatment of hypertensive emergencies.

Beta-adrenoreceptor blockade can cause reduction of intraocular pressure. Patients should be told that INDERAL may interfere with the glaucoma screening test. Withdrawal may lead to a return of increased intraocular pressure.

CLINICAL LABORATORY TESTS: Elevated blood urea levels in patients with severe heart disease, elevated serum transaminase, alkaline phosphatase, lactate dehydrogenase.

DRUG INTERACTIONS: Patients receiving catecholamine-depleting drugs such as reserpine should be closely observed if INDERAL is administered. The added catecholamine-blocking action may produce an excessive reduction of resting sympathetic nervous activity resulting in hypotension, marked bradycardia, vertigo, syncopal attacks, or orthostatic hypotension.

Caution should be exercised when patients receiving a beta blocker are administered a calcium-channel-blocking drug, especially intravenous verapamil, as both agents may depress myocardial contractility or atrioventricular conduction. On rare occasions, the concomitant intravenous use of a beta blocker and verapamil has resulted in serious adverse reactions, especially in patients with severe cardiomyopathy, congestive heart failure or recent myocardial infarction.

Aluminum hydroxide gel greatly reduces intestinal absorption of propranolol.

Ethanol slows the rate of absorption of propranolol.

Phenytoin, phenobarbitone, and *rifampin* accelerate propranolol clearance.

Chlorpromazine, when used concomitantly with propranolol, results in increased plasma levels of both drugs.

Antipyrine and *lidocaine* have reduced clearance when used concomitantly with propranolol.

Thyroxine may result in a lower than expected T_3 concentration when used concomitantly with propranolol.

Cimetidine decreases the hepatic metabolism of propranolol, delaying elimination and increasing blood levels.

Theophylline clearance is reduced when used concomitantly with propranolol.

CARCINOGENESIS, MUTAGENESIS, IMPAIRMENT OF FERTILITY: There was no evidence of significant drug-induced toxicity in rats or mice, employing doses up to 150 mg/kg/day over an 18-month period. There were no drug-related tumorigenic effects at any dosage levels. No impairment of fertility attributable to the drug was seen in animal reproductive studies.

PREGNANCY: Pregnancy Category C. INDERAL has been shown to be embryotoxic in animal studies at doses about 10 times greater than the maximum recommended human dose. There are no adequate and well-controlled studies in pregnant women. Use during pregnancy only if the potential benefit justifies the potential risk to the fetus.

NURSING MOTHERS: INDERAL is excreted in human milk. Exercise caution when INDERAL is administered to a nursing woman.

PEDIATRIC USE: Safety and effectiveness in children have not been established.

ADVERSE REACTIONS. Most adverse effects have been mild and transient and have rarely required the withdrawal of therapy.

Cardiovascular: Bradycardia; congestive heart failure; intensification of AV block; hypotension; paresthesia of hands; thrombocytopenic purpura; arterial insufficiency, usually of the Raynaud type.

Central Nervous System: Light-headedness; mental depression manifested by insomnia, lassitude, weakness, fatigue; reversible mental depression progressing to catatonia; visual disturbances; hallucinations; vivid dreams; an acute reversible syndrome characterized by disorientation for time and place, short-term memory loss, emotional lability, slightly clouded sensorium, and decreased performance on neuropsychometrics. For immediate formulations, fatigue, lethargy, and vivid dreams appear dose related.

Gastrointestinal: Nausea, vomiting, epigastric distress, abdominal cramping, diarrhea, constipation, mesenteric arterial thrombosis, ischemic colitis.

Allergic: Pharyngitis and agranulocytosis, erythematous rash, fever combined with aching and sore throat, laryngospasm, and respiratory distress.

Respiratory: Bronchospasm.

Hematologic: Agranulocytosis, nonthrombocytopenic purpura, thrombocytopenic purpura.

Auto-Immune: In extremely rare instances, systemic lupus erythematosus has been reported.

Miscellaneous: Alopecia, LE-like reactions, psoriasiform rashes, dry eyes, male impotence, and Peyronie's disease have been reported rarely. The oculomucocutaneous reactions associated with practolol have not been reported with propranolol.

DOSAGE AND ADMINISTRATION: INDERAL LA provides propranolol hydrochloride in a sustained-release capsule for administration once daily. If patients are switched from INDERAL Tablets to INDERAL LA Capsules, care should be taken to assure that the desired therapeutic effect is maintained. INDERAL LA should not be considered a simple mg-for-mg substitute for INDERAL. INDERAL LA has different kinetics and produces lower blood levels. Retitration may be necessary, especially to maintain effectiveness at the end of the 24-hour dosing interval.

For management of hypertension, angina pectoris, migraine, and hypertrophic subaortic stenosis the dosage must be individualized. Usual initial dose is 80 mg once daily.

If treatment is to be discontinued, reduce dosage gradually over a period of a few weeks (see WARNINGS).

PEDIATRIC DOSAGE – At this time the data on the use of the drug in this age group are too limited to permit adequate directions for use.

OVERDOSAGE. INDERAL is not significantly dialyzable. If ingestion is, or may have been, recent, evacuate gastric contents, taking care to prevent pulmonary aspiration.

BRADYCARDIA: Administer atropine (0.25 to 1.0 mg); if no response to vagal blockade, administer isoproterenol cautiously. CARDIAC FAILURE: digitalization and diuretics. HYPOTENSION: vasopressors, eg, levarterenol or epinephrine (there is evidence that epinephrine is the drug of choice). BRONCHOSPASM: administer isoproterenol and aminophylline.

The appearance of these capsules is a registered trademark of Ayerst Laboratories.

WYETH-AYERST LABORATORIES

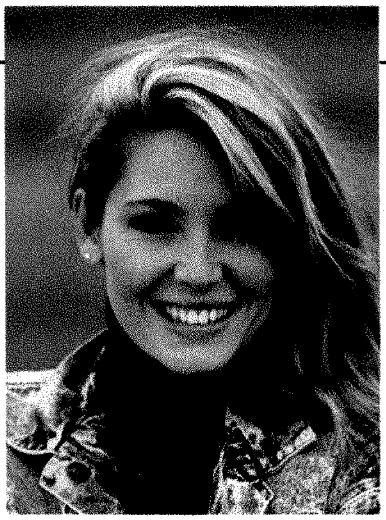
Stop the daily threat of migraine...

"Violent Passages" is a time-lapse portrayal by Louise Woodard depicting her own migraine headache sequence as she sees it. Her work focuses on the pain surrounding her eye and the confusion she feels as a result of the migraine.

with a daily dose of prevention.



Migraine. It's agonizing, debilitating, unpredictable. And abortive therapies often provide inadequate relief or cause troublesome side effects for your patients.

Proven qd prophylaxis at recommended doses.

Only INDERAL® LA provides once-daily preventive therapy— to significantly reduce both frequency and severity of common migraine. **Start with 80 mg/day and titrate to an effective dose — usually 160 to 240 mg once daily.**

Well-tolerated, long-term efficacy.

For patients whose day-to-day lives are undermined by anticipation of migraine, INDERAL LA can offer an improved sense of control. Because the only thing worse than the pain of migraine is the threat of it.

ONCE-DAILY
INDERAL® LA
(PROPRANOLOL HCl)
LONG ACTING CAPSULES
60, 80, 120, 160 mg

Another day without migraine.

Please see next page for brief summary of prescribing information.

INDERAL LA should not be used in the presence of congestive heart failure, sinus bradycardia, cardiogenic shock, heart block greater than first degree, and bronchial asthma.

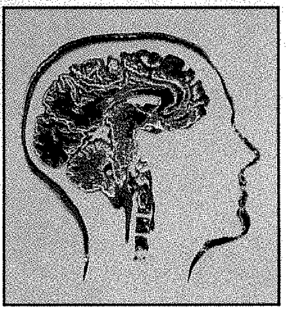
THROUGH A CALCIUM-MODULATING MECHANISM OF ACTION



CEREBROSELECTIVE

NIMOTOP®

nimodipine/Miles

CAPSULES 30 mg

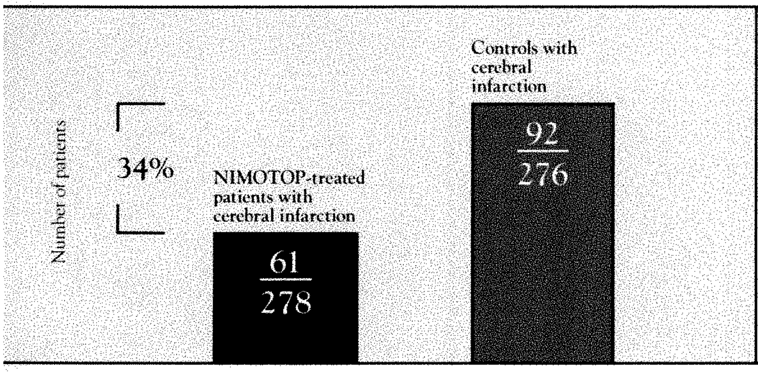
REDUCES INCIDENCE OF CEREBRAL NFARCTION IN PATIENTS FOLLOWING SUBARACHNOID HEMORRHAGE

---

n the largest study to date, NIMOTOP demonstrated a significant eduction in incidence of cerebral infarction[1]

- Twenty-two percent (61/278) of NIMOTOP-treated patients experienced cerebral infarction vs. 33% (92/276) of controls
- NIMOTOP reduced the incidence of cerebral infarction by 34%

hirty-four percent reduction in incidence of cerebral infarction with IMOTOP-treated patients vs. controls (n=554; p=0.003)[1]*



*90% of patients in this study were Hunt and Hess Grades I-III.

Dose: 60 mg (two 30 mg liquid-filled capsules) every 4 hours for 21 days commencing within 96 hours of SAH.

Adapted from Pickard, et al.[1]

IMOTOP modulates calcium influx to promote cerebral perfusion, nd may directly protect neurons[2-5]

[In animals] The beneficial cytoprotective effect of nimodipine, probably related to normalization f calcium homeostasis and blood-brain barrier permeability after ischemia, may reflect both ascular and cellular sites of action."[6]

azarewicz JW, et al. *Stroke* 1989.

[In humans] The data thus suggest that nimodipine neither prevents nor reverses cerebral asospasm. Calcium channel blockers such as nimodipine may have an effect on cerebral arterioles hat are below the limits of resolution of angiography...."[1]

ickard JD, et al. *Br Med J* 1989.

CEREBROSELECTIVE

NIMOTOP®

nimodipine/Miles

CAPSULES 30 mg

NIMOTOP REDUCES THE INCIDENCE OF CEREBRAL NFARCTION FOLLOWING SUBARACHNOID HEMORRHAGI

EF SUMMARY
OTOP® (nimodipine/Miles) CAPSULES
Oral Use

ICATIONS AND USAGE

imotop® (nimodipine) is indicated for the improvement of neurological deficits due to spasm wing subarachnoid hemorrhage from ruptured congenital intracranial aneurysms in patients are in good neurological condition post-ictus (e.g. Hunt and Hess Grades I-III). Oral otop® therapy should begin within 96 hours of the subarachnoid hemorrhage and continue 1 days.

NTRAINDICATIONS

one known.

CAUTIONS

eneral: Blood Pressure: Nimodipine has the hemodynamic effects expected of a calcium nnel blocker, although they are generally not marked. In patients with subarachnoid hemor- e given Nimotop® in clinical studies, about 5% were reported to have had lowering of the d pressure and about 1% left the study because of this (not all could be attributed to odipine). Nevertheless, blood pressure should be carefully monitored during treatment with otop® based on its known pharmacology and the known effects of calcium channel blockers. epatic Disease: The metabolism of Nimotop® is decreased in patients with impaired hepatic tion. Such patients should have their blood pressure and pulse rate monitored closely and ld be given a lower dose (see Dosage and Administration).

aboratory Test Interactions: None known.

rug Interaction: It is possible that the cardiovascular action of other calcium channel kers could be enhanced by the addition of Nimotop®.

Europe, Nimotop® was observed to occasionally intensify the effect of antihypertensive pounds taken concomitantly by patients suffering from hypertension: this phenomenon was observed in North American clinical trials.

arcinogenesis, Mutagenesis, Impairment of Fertility: In a two-year study, higher incidences denocarcinoma of the uterus and Leydig-cell adenoma of the testes were observed in rats n a diet containing 1800 ppm nimodipine (equivalent to 91 to 121 mg/kg/day nimodipine) in placebo controls. The differences were not statistically significant; however, the higher s were well within historical control range for these tumors in the Wistar strain. Nimodipine found not to be carcinogenic in a 91-week mouse study but the high dose of 1800 ppm odipine-in-feed (546 to 774 mg/kg/day) shortened the life expectancy of the animals. agenic studies, including the Ames, micronucleus and dominant lethal tests were negative. imodipine did not impair the fertility and general reproductive performance of male and ale Wistar rats following oral doses of up to 30 mg/kg/day when administered daily for more 10 weeks in the males and 3 weeks in the females prior to mating and continued to day 7 of nancy. This dose in a rat is about 4 times the equivalent clinical dose of 60 mg q4h in a 50 kg ent.

regnancy: Pregnancy Category C. Nimodipine has been shown to have a teratogenic effect imalayan rabbits. Incidences of malformations and stunted fetuses were increased at oral (by ge) doses of 1 and 10 mg/kg/day administered from day 6 through day 18 of pregnancy but not 0 mg/kg/day in one of two identical rabbit studies. In the second study an increased incidence unted fetuses was seen at 1.0 mg/kg/day but not at higher doses. Nimodipine was embryo- c, causing resorption and stunted growth of fetuses, in Long Evans rats at 100 mg/kg/day inistered by gavage from day 6 through day 15 of pregnancy. In two other rat studies, doses of ng/kg/day nimodipine administered by gavage from day 16 of gestation and continued until ifice (day 20 of pregnancy or day 21 post partum) were associated with higher incidences of etal variation, stunted fetuses and stillbirths but no malformations. There are no adequate well controlled studies in pregnant women to directly assess the effect on human fetuses. odipine should be used during pregnancy only if the potential benefit justifies the potential to the fetus.

ursing Mothers: Nimodipine and/or its metabolites have been shown to appear in rat milk oncentrations much higher than in maternal plasma. It is not known whether the drug is reted in human milk. Because many drugs are excreted in human milk, nursing mothers are ised not to breast feed their babies when taking the drug.

ediatric Use: Safety and effectiveness in children have not been established.

VERSE REACTIONS

dverse experiences were reported by 92 of 823 patients with subarachnoid hemorrhage 2%) who were given nimodipine. The most frequently reported adverse experience was reased blood pressure in 4.4% of these patients. Twenty-nine of 479 (6.1%) placebo treated ents also reported adverse experiences. The events reported with a frequency greater than 1% displayed below by dose.

DOSE q4h
Number of Patients (%)

	Nimodipine					Placebo
n/Symptom	0.35 mg/kg (n = 82)	30 mg (n = 71)	60 mg (n = 494)	90 mg (n = 172)	120 mg (n = 4)	(n = 479)
reased Blood Pressure	1 (1.2)	0	19 (3.8)	14 (8.1)	2 (50.0)	6 (1.2)
ormal Liver Function Test	1 (1.2)	0	2 (0.4)	1 (0.6)	0	7 (1.5)
ma	0	0	2 (0.4)	2 (1.2)	0	3 (0.6)
rrhea	0	3 (4.2)	0	3 (1.7)	0	3 (0.6)
h	2 (2.4)	0	3 (0.6)	2 (1.2)	0	3 (0.6)
dache	0	1 (1.4)	6 (1.2)	0	0	1 (0.2)
strointestinal Symptoms	2 (2.4)	0	0	2 (1.2)	0	0

DOSE q4h
Number of Patients (%)

	Nimodipine					Placel
Sign/Symptom	0.35 mg/kg (n = 82)	30 mg (n = 71)	60 mg (n = 494)	90 mg (n = 172)	120 mg (n = 4)	(n = 4
Nausea	1 (1.2)	1 (1.4)	6 (1.2)	1 (0.6)	0	0
Dyspnea	1 (1.2)	0	0	0	0	0
EKG Abnormalities	0	1 (1.4)	0	1 (0.6)	0	0
Tachycardia	0	1 (1.4)	0	0	0	0
Bradycardia	0	0	5 (1.0)	1 (0.6)	0	0
Muscle Pain/Cramp	0	1 (1.4)	1 (0.2)	1 (0.6)	0	0
Acne	0	1 (1.4)	0	0	0	0
Depression	0	1 (1.4)	0	0	0	0

There were no other adverse experiences reported by the patients who were given 0.35 mg q4h, 30 mg q4h or 120 mg q4h. Adverse experiences with an incidence rate of less than 1% in 60 mg q4h dose group were: hepatitis; itching; gastrointestinal hemorrhage; thrombocytoper anemia; palpitations; vomiting; flushing; diaphoresis; wheezing; phenytoin toxicity; lighth dedness; dizziness; rebound vasospasm; jaundice; hypertension; hematoma.

Adverse experiences with an incidence rate less than 1% in the 90 mg q4h dose group we itching; gastrointestinal hemorrhage; thrombocytopenia; neurological deterioration; vomiti diaphoresis; congestive heart failure; hyponatremia; decreasing platelet count; dissemina intravascular coagulation; deep vein thrombosis.

As can be seen from the table, side effects that appear related to nimodipine use based increased incidence with higher dose or a higher rate compared to placebo control, inclu decreased blood pressure, edema and headaches which are known pharmacologic action calcium channel blockers. It must be noted, however, that SAH is frequently accompanied alterations in consciousness which lead to an under reporting of adverse experiences. Patie who received nimodipine in clinical trials for other indications reported flushing (2.1 headache (4.1%) and fluid retention (0.3%), typical responses to calcium channel blockers. calcium channel blocker, nimodipine may have the potential to exacerbate heart failure susceptible patients or to interfere with A-V conduction, but these events were not observed

No clinically significant effects on hematologic factors, renal or hepatic function or carbo drate metabolism have been causally associated with oral nimodipine. Isolated cases of non- ing elevated serum glucose levels (0.8%), elevated LDH levels (0.4%), decreased platelet cou (0.3%), elevated alkaline phosphatase levels (0.2%) and elevated SGPT levels (0.2%) have b reported rarely.

OVERDOSAGE

There have been no reports of overdosage from the oral administration of Nimotop®. Sy toms of overdosage would be expected to be related to cardiovascular effects such as exces peripheral vasodilation with marked systemic hypotension. Clinically significant hypotens due to Nimotop® overdosage may require active cardiovascular support. Norepinephrine dopamine may be helpful in restoring blood pressure. Since Nimotop® is highly protein-bou dialysis is not likely to be of benefit.

DOSAGE AND ADMINISTRATION

Nimotop® is given orally in the form of ivory colored, soft gelatin 30 mg capsules for subara noid hemorrhage.

The oral dose is 60 mg (two 30 mg capsules) every 4 hours for 21 consecutive days. Nimotop® therapy should commence within 96 hours of the subarachnoid hemorrhage.

If the capsule cannot be swallowed, e.g., at the time of surgery, or if the patient is unconsci a hole should be made in both ends of the capsule with an 18 gauge needle, and the contents of capsule extracted into a syringe. The contents should then be emptied into the patient's in naso-gastric tube and washed down the tube with 30 mL of normal saline (0.9%).

Patients with hepatic failure have substantially reduced clearance and approximately dou C_{max}. Dosage should be reduced to 30 mg every 4 hours, with close monitoring of blood pres and heart rate.

HANS BERGER Clinical Neurophysiology Symposium

A COMPREHENSIVE UPDATE OF RECENT ADVANCES FOR PHYSICIANS AND TECHNICIANS

May 20-21, 1991

Topics in EEG, Epilepsy, and Epilepsy Surgery:
• Anti-Convulsant Drug Therapy • The Neurophysiology of the Human Supplementary Motor Area • A Critical Review of Seizure and Epilepsy Classifications • The Use of Cerebral Cortex Recordings in the Diagnosis and Surgical Treatment of Seizures • The Use of EEG in the Clinical Setting • An Update on Recent Advances on Status Epilepticus

Hans Berger Lecturer: **Hans Lueders, M.D., Ph.D.**
MCV Distinguished Scholar: **Eli W. Goldensohn, M.D.**

Guest Faculty: Jerald Chiles, R.EEG T. W. Edwin Dodson, M.D.
Ellen R. Grass, L.L.D. John Pellock, M.D.
L. F. Quesney, M.D. David Treiman, M.D.

Accreditation: 12 Category 1 C.M.E. and 1.2 Units of C.E.U.

Fee: $275 for Physicians, $130 for Residents, Fellows and Technologists

Tegretol®

200 mg scored tablets
100 mg chewable tablets

carbamazepine USP

...because after seizure control, there's a lot of living to do!

TEGRETOL is indicated for children 6 years and older and adults.

Because of the potential for serious hematologic adverse reactions, it is important that you become thoroughly familiar with the full Prescribing Information for TEGRETOL on the next page, especially the boxed warning.

Tegretol®

carbamazepine USP

Chewable Tablets of 100 mg—red-speckled, pink Tablets of 200 mg—pink

WARNING
APLASTIC ANEMIA AND AGRANULOCYTOSIS HAVE BEEN REPORTED IN ASSOCIATION WITH THE USE OF TEGRETOL. DATA FROM A POPULATION-BASED CASE CONTROL STUDY DEMONSTRATE THAT THE RISK OF DEVELOPING THESE REACTIONS IS 5-8 TIMES GREATER THAN IN THE GENERAL POPULATION. HOWEVER, THE OVERALL RISK OF THESE REACTIONS IN THE UNTREATED GENERAL POPULATION IS LOW, APPROXIMATELY SIX PATIENTS PER ONE MILLION POPULATION PER YEAR FOR AGRANULOCYTOSIS AND TWO PATIENTS PER ONE MILLION POPULATION PER YEAR FOR APLASTIC ANEMIA.

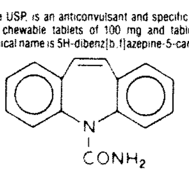
ALTHOUGH REPORTS OF TRANSIENT OR PERSISTENT DECREASED PLATELET OR WHITE BLOOD CELL COUNTS ARE NOT UNCOMMON IN ASSOCIATION WITH THE USE OF TEGRETOL, DATA ARE NOT AVAILABLE TO ESTIMATE ACCURATELY THEIR INCIDENCE OR OUTCOME. HOWEVER, THE VAST MAJORITY OF THE CASES OF LEUKOPENIA HAVE NOT PROGRESSED TO THE MORE SERIOUS CONDITIONS OF APLASTIC ANEMIA OR AGRANULOCYTOSIS.

BECAUSE OF THE VERY LOW INCIDENCE OF AGRANULOCYTOSIS AND APLASTIC ANEMIA, THE VAST MAJORITY OF MINOR HEMATOLOGIC CHANGES OBSERVED IN MONITORING OF PATIENTS ON TEGRETOL ARE UNLIKELY TO SIGNAL THE OCCURRENCE OF EITHER ABNORMALITY. NONETHELESS, COMPLETE PRETREATMENT HEMATOLOGICAL TESTING SHOULD BE OBTAINED AS A BASELINE. IF A PATIENT IN THE COURSE OF TREATMENT EXHIBITS LOW OR DECREASED WHITE BLOOD CELL OR PLATELET COUNTS, THE PATIENT SHOULD BE MONITORED CLOSELY. DISCONTINUATION OF THE DRUG SHOULD BE CONSIDERED IF ANY EVIDENCE OF SIGNIFICANT BONE MARROW DEPRESSION DEVELOPS.

Before prescribing Tegretol, the physician should be thoroughly familiar with the details of this prescribing information, particularly regarding use with other drugs, especially those which accentuate toxicity potential.

DESCRIPTION

Tegretol, carbamazepine USP, is an anticonvulsant and specific analgesic for trigeminal neuralgia, available as chewable tablets of 100 mg and tablets of 200 mg for oral administration. Its chemical name is 5H-dibenz[b,f]azepine-5-carboxamide, and its structural formula is:



Carbamazepine USP is a white to off-white powder, practically insoluble in water and soluble in alcohol and in acetone. Its molecular weight is 236.27.

Inactive Ingredients. Colloidal silicon dioxide, FD&C Red No. 3 (chewable tablets only), FD&C Red No. 40 (200-mg tablets only), flavoring (chewable tablets only), gelatin, glycerin, magnesium stearate, sodium starch glycolate (chewable tablets only), starch, stearic acid, and sucrose (chewable tablets only).

CLINICAL PHARMACOLOGY

In controlled clinical trials, Tegretol has been shown to be effective in the treatment of psychomotor and grand mal seizures, as well as trigeminal neuralgia.

It has demonstrated anticonvulsant properties in rats and mice with electrically and chemically induced seizures. It appears to act by reducing polysynaptic responses and blocking the post-tetanic potentiation. Tegretol greatly reduces or abolishes pain induced by stimulation of the infraorbital nerve in cats and rats. It depresses thalamic potential and bulbar and polysynaptic reflexes, including the linguomandibular reflex in cats. Tegretol is chemically unrelated to other anticonvulsants or other drugs used to control the pain of trigeminal neuralgia. The mechanism of action remains unknown.

Tegretol tablets are adequately absorbed after oral administration at a slower rate than a solution, thus avoiding undesirably high peak concentrations. Tegretol chewable tablets may produce higher peak levels than the same dose given as regular tablets. Tegretol in blood is 76% bound to plasma proteins. Plasma levels of Tegretol are variable and may range from 0.5-25 μg/ml, with no apparent relationship to the daily intake of the drug. Usual adult therapeutic levels are between 4 and 12 μg/ml. Following oral administration, serum levels peak at 4 to 5 hours. The CSF/serum ratio is 0.22, similar to the 22% unbound Tegretol in serum. Because Tegretol may induce its own metabolism, the half-life is also variable. Initial half-life values range from 25-65 hours, with 12-17 hours on repeated doses. Tegretol is metabolized in the liver. After oral administration of ^{14}C-carbamazepine, 72% of the administered radioactivity was found in the urine and 28% in the feces. This urinary radioactivity was composed largely of hydroxylated and conjugated metabolites, with only 3% of unchanged Tegretol. Transplacental passage of Tegretol is rapid (30 to 60 minutes), and the drug is accumulated in fetal tissues, with higher levels found in liver and kidney than in brain and lungs.

INDICATIONS AND USAGE

Epilepsy: Tegretol is indicated for use as an anticonvulsant drug. Evidence supporting efficacy of Tegretol as an anticonvulsant was derived from active drug-controlled studies that enrolled patients with the following seizure types:

1. Partial seizures with complex symptomatology (psychomotor, temporal lobe). Patients with these seizures appear to show greater improvement than those with other types.
2. Generalized tonic-clonic seizures (grand mal).
3. Mixed seizure patterns which include the above, or other partial or generalized seizures.

Absence seizures (petit mal) do not appear to be controlled by Tegretol (see PRECAUTIONS, General).

Trigeminal Neuralgia: Tegretol is indicated in the treatment of the pain associated with true trigeminal neuralgia.

Beneficial results have also been reported in glossopharyngeal neuralgia.

This drug is not a simple analgesic and should not be used for the relief of trivial aches or pains.

CONTRAINDICATIONS

Tegretol should not be used in patients with a history of previous bone marrow depression, hypersensitivity to the drug, or known sensitivity to any of the tricyclic compounds, such as amitriptyline, desipramine, imipramine, protriptyline, nortriptyline, etc. Likewise, on theoretical grounds its use with monoamine oxidase inhibitors is not recommended. Before administration of Tegretol, MAO inhibitors should be discontinued for a minimum of fourteen days, or longer if the clinical situation permits.

WARNINGS

Patients with a history of adverse hematologic reaction to any drug may be particularly at risk.

Severe dermatologic reactions including toxic epidermal necrolysis (Lyell's syndrome) and Stevens-Johnson syndrome, have been reported with Tegretol. These reactions have been extremely rare. However, a few fatalities have been reported.

Tegretol has shown mild anticholinergic activity; therefore, patients with increased intraocular pressure should be closely observed during therapy.

Because of the relationship of the drug to other tricyclic compounds, the possibility of activation of a latent psychosis and, in elderly patients, of confusion or agitation should be borne in mind.

PRECAUTIONS

General: Before initiating therapy, a detailed history and physical examination should be made.

Tegretol should be used with caution in patients with a mixed seizure disorder that includes atypical absence seizures, since in these patients Tegretol has been associated with increased frequency of generalized convulsions (see INDICATIONS AND USAGE).

Therapy should be prescribed only after critical benefit-to-risk appraisal in patients with a history of cardiac, hepatic or renal damage, adverse hematologic reaction to other drugs, or interrupted courses of therapy with Tegretol.

Information for Patients: Patients should be made aware of the early toxic signs and symptoms of a potential hematologic problem, such as fever, sore throat, ulcers in the mouth, easy bruising, petechial or purpuric hemorrhage, and should be advised to report to the physician immediately if any such signs or symptoms appear.

Since dizziness and drowsiness may occur, patients should be cautioned about the hazards of operating machinery or automobiles or engaging in other potentially dangerous tasks.

Laboratory Tests: Complete pretreatment blood counts, including platelets and possibly reticulocytes and serum iron, should be obtained as a baseline. If a patient in the course of treatment exhibits low or decreased white blood cell or platelet counts, the patient should be monitored closely. Discontinuation of the drug should be considered if any evidence of significant bone marrow depression develops.

Baseline and periodic evaluations of liver function, particularly in patients with a history of liver disease, must be performed during treatment with this drug since liver damage may occur. The drug should be discontinued immediately in cases of aggravated liver dysfunction or active liver disease.

Baseline and periodic eye examinations, including slit-lamp, funduscopy and tonometry, are recommended since many phenothiazines and related drugs have been shown to cause eye changes.

Baseline and periodic complete urinalysis and BUN determinations are recommended for patients treated with this agent because of observed renal dysfunction.

Monitoring of blood levels (see CLINICAL PHARMACOLOGY) has increased the efficacy and safety of anticonvulsants. This monitoring may be particularly useful in cases of dramatic increase in seizure frequency and for verification of compliance. In addition, measurement of drug serum levels may aid in determining the cause of toxicity when more than one medication is being used.

Thyroid function tests have been reported to show decreased values with Tegretol administered alone.

Hyponatremia has been reported in association with Tegretol use, either alone or in combination with other drugs.

Drug Interactions: The simultaneous administration of phenobarbital, phenytoin, or primidone, or a combination of two, produces a marked lowering of serum levels of Tegretol. The effect of valproic acid on Tegretol blood levels is not clearly established, although an increase in the ratio of active 10, 11-epoxide metabolite to parent compound is a consistent finding.

The half-lives of phenytoin, warfarin, doxycycline, and theophylline were significantly shortened when administered concurrently with Tegretol. Haloperidol and valproic acid serum levels may be reduced when these drugs are administered with Tegretol. The doses of these drugs may therefore have to be increased when Tegretol is added to the therapeutic regimen.

Concomitant administration of Tegretol with erythromycin, cimetidine, propoxyphene, isoniazid or calcium channel blockers has been reported to result in elevated plasma levels of carbamazepine resulting in toxicity in some cases. Also, concomitant administration of carbamazepine and lithium may increase the risk of neurotoxic side effects.

Alterations of thyroid function have been reported in combination therapy with other anticonvulsant medications.

Breakthrough bleeding has been reported among patients receiving concomitant oral contraceptives and their reliability may be adversely affected.

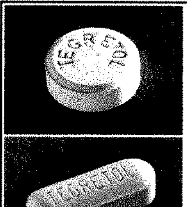
Carcinogenesis, Mutagenesis, Impairment of Fertility: Carbamazepine, when administered to Sprague-Dawley rats for two years in the diet at doses of 25, 75, and 250 mg/kg/day, resulted in a dose-related increase in the incidence of hepatocellular tumors in females and of benign interstitial cell adenomas in the testes of males.

Carbamazepine must, therefore, be considered to be carcinogenic in Sprague-Dawley rats. Bacterial and mammalian mutagenicity studies using carbamazepine produced negative results. The significance of these findings relative to the use of carbamazepine in humans is, at present, unknown.

Pregnancy Category C: Tegretol has been shown to have adverse effects in reproduction studies in rats when given orally in dosages 10-25 times the maximum human daily dosage of 1200 mg. In rat teratology studies, 2 of 135 offspring showed kinked ribs at 250 mg/kg and 4 of 119 offspring at 650 mg/kg showed other anomalies (cleft palate, 1; talipes, 1; anophthalmos, 2). In reproduction studies in rats, nursing offspring demonstrated a lack of weight gain and an unkempt appearance at a maternal dosage level of 200 mg/kg.

There are no adequate and well-controlled studies in pregnant women. Epidemiological data suggest that there may be an association between the use of carbamazepine during pregnancy and congenital malformations, including spina bifida. Tegretol should be used during pregnancy only if the potential benefit justifies the potential risk to the fetus.

Retrospective case reviews suggest that, compared with monotherapy, there may be a higher prevalence of teratogenic effects associated with the use of anticonvulsants in combination therapy. Therefore, monotherapy is recommended for pregnant women.



Only TEGRETOL,
brand of carbamazepine,
provides the prescribing
flexibility of a 100-mg scored
chewable tablet, as well as
a 200-mg scored tablet.

It is important to note that anticonvulsant drugs should not be discontinued in patients in whom the drug is administered to prevent major seizures because of the strong possibility of precipitating status epilepticus with attendant hypoxia and threat to life. In individual cases where the severity and frequency of the seizure disorder are such that removal of medication does not pose a serious threat to the patient, discontinuation of the drug may be considered prior to and during pregnancy, although it cannot be said with any confidence that even minor seizures do not pose some hazard to the developing embryo or fetus.

Labor and Delivery: The effect of Tegretol on human labor and delivery is unknown.

Nursing Mothers: During lactation, concentration of Tegretol in milk is approximately 60% of the maternal plasma concentration.

Because of the potential for serious adverse reactions in nursing infants from carbamazepine, a decision should be made whether to discontinue nursing or to discontinue the drug, taking into account the importance of the drug to the mother.

Pediatric Use: Safety and effectiveness in children below the age of 6 years have not been established.

ADVERSE REACTIONS

If adverse reactions are of such severity that the drug must be discontinued, the physician must be aware that abrupt discontinuation of any anticonvulsant drug in a responsive epileptic patient may lead to seizures or even status epilepticus with its life-threatening hazards.

The most severe adverse reactions have been observed in the hemopoietic system (see boxed WARNING), the skin and the cardiovascular system.

The most frequently observed adverse reactions, particularly during the initial phases of therapy, are dizziness, drowsiness, unsteadiness, nausea, and vomiting. To minimize the possibility of such reactions, therapy should be initiated at the low dosage recommended.

The following additional adverse reactions have been reported:

Hemopoietic System. Aplastic anemia, agranulocytosis, pancytopenia, bone marrow depression, thrombocytopenia, leukopenia, leukocytosis, eosinophilia, acute intermittent porphyria.

Skin. Pruritic and erythematous rashes, urticaria, toxic epidermal necrolysis (Lyell's syndrome) (see WARNINGS), Stevens-Johnson syndrome (see WARNINGS), photosensitivity reactions, alterations in skin pigmentation, exfoliative dermatitis, erythema multiforme and nodosum, purpura, aggravation of disseminated lupus erythematosus, alopecia, and diaphoresis. In certain cases, discontinuation of therapy may be necessary.

Cardiovascular System. Congestive heart failure, edema, aggravation of hypertension, hypotension, syncope and collapse, aggravation of coronary artery disease, arrhythmias and AV block, primary thrombophlebitis, recurrence of thrombophlebitis, and adenopathy or lymphadenopathy.

Some of these cardiovascular complications have resulted in fatalities. Myocardial infarction has been associated with other tricyclic compounds.

Liver. Abnormalities in liver function tests, cholestatic and hepatocellular jaundice, hepatitis.

Respiratory System. Pulmonary hypersensitivity characterized by fever, dyspnea, pneumonitis or pneumonia.

Genitourinary System. Urinary frequency, acute urinary retention, oliguria with elevated blood pressure, azotemia, renal failure, and impotence. Albuminuria, glycosuria, elevated BUN and microscopic deposits in the urine have also been reported.

Testicular atrophy occurred in rats receiving Tegretol orally from 4 to 52 weeks at dosage levels of 50 to 400 mg/kg/day. Additionally, rats receiving Tegretol in the diet for two years at dosage levels of 25, 75, and 250 mg/kg/day had a dose-related incidence of testicular atrophy and aspermatogenesis. In dogs, it produced a brownish discoloration, presumably a metabolite, in the urinary bladder at dosage levels of 50 mg/kg and higher. Relevance of these findings to humans is unknown.

Nervous System. Dizziness, drowsiness, disturbances of coordination, confusion, headache, fatigue, blurred vision, visual hallucinations, transient diplopia, oculomotor disturbances, nystagmus, speech disturbances, abnormal involuntary movements, peripheral neuritis and paresthesias, depression with agitation, talkativeness, tinnitus, and hyperacusis.

There have been reports of associated paralysis and other symptoms of cerebral arterial insufficiency, but the exact relationship of these reactions to the drug has not been established.

Digestive System. Nausea, vomiting, gastric distress and abdominal pain, diarrhea, constipation, anorexia, and dryness of the mouth and pharynx, including glossitis and stomatitis.

Eyes. Scattered, punctate, cortical lens opacities, as well as conjunctivitis have been reported. Although a direct causal relationship has not been established, many phenothiazines and related drugs have been shown to cause eye changes.

Musculoskeletal System. Aching joints and muscles, and leg cramps.

Metabolism. Fever and chills. Inappropriate antidiuretic hormone (ADH) secretion syndrome has been reported. Cases of frank water intoxication, with decreased serum sodium (hyponatremia) and confusion, have been reported in association with Tegretol use (see PRECAUTIONS, Laboratory Tests).

Other. Isolated cases of a lupus erythematosus-like syndrome have been reported. There have been occasional reports of elevated levels of cholesterol, HDL cholesterol and triglycerides in patients taking anticonvulsants.

A case of aseptic meningitis, accompanied by myoclonus and peripheral eosinophilia, has been reported in a patient taking carbamazepine in combination with other medications. The patient was successfully dechallenged, and the meningitis reappeared upon rechallenge with carbamazepine.

DRUG ABUSE AND DEPENDENCE

No evidence of abuse potential has been associated with Tegretol, nor is there evidence of psychological or physical dependence in humans.

OVERDOSAGE

Acute Toxicity

Lowest known lethal dose: adults, >60 g (39-year-old man). Highest known doses survived: adults, 30 g (31-year-old woman); children, 10 g (6-year-old boy); small children, 5 g (3-year-old girl).

Oral LD50 in animals (mg/kg): mice, 1100-3750; rats, 3850-4025; rabbits, 1500-2680; guinea pigs, 920.

Signs and Symptoms

The first signs and symptoms appear after 1-3 hours. Neuromuscular disturbances are the most prominent. Cardiovascular disorders are generally milder, and severe cardiac complications occur only when very high doses (>60 g) have been ingested.

Respiration. Irregular breathing, respiratory depression.

Cardiovascular System. Tachycardia, hypotension or hypertension, shock, conduction disorders.

Nervous System and Muscles. Impairment of consciousness ranging in severity to deep coma. Convulsions, especially in small children. Motor restlessness, muscular twitching, tremor, athetoid movements, opisthotonos, ataxia, drowsiness, dizziness, mydriasis, nystagmus, adiadochokinesia, ballism, psychomotor disturbances, dysmetria. Initial hyperreflexia, followed by hyporeflexia.

Gastrointestinal Tract. Nausea, vomiting.

Kidneys and Bladder. Anuria or oliguria, urinary retention.

Laboratory Findings. Isolated instances of overdosage have included leukocytosis, reduced leukocyte count, glycosuria and acetonuria. EEG may show dysrhythmias.

Combined Poisoning. When alcohol, tricyclic antidepressants, barbiturates or hydantoins are taken at the same time, the signs and symptoms of acute poisoning with Tegretol may be aggravated or modified.

Treatment

The prognosis in cases of severe poisoning is critically dependent upon prompt elimination of the drug, which may be achieved by inducing vomiting, irrigating the stomach, and by taking appropriate steps to diminish absorption. If these measures cannot be implemented without risk on the spot, the patient should be transferred at once to a hospital, while ensuring that vital functions are safeguarded. There is no specific antidote.

Elimination of the Drug. Induction of vomiting.

Gastric lavage. Even when more than 4 hours have elapsed following ingestion of the drug, the stomach should be repeatedly irrigated, especially if the patient has also consumed alcohol.

Measures to Reduce Absorption. Activated charcoal, laxatives.

Measures to Accelerate Elimination. Forced diuresis.

Dialysis is indicated only in severe poisoning associated with renal failure. Replacement transfusion is indicated in severe poisoning in small children.

Respiratory Depression. Keep the airways free; resort, if necessary, to endotracheal intubation, artificial respiration, and administration of oxygen.

Hypotension, Shock. Keep the patient's legs raised and administer a plasma expander. If blood pressure fails to rise despite measures taken to increase plasma volume, use of vasoactive substances should be considered.

Convulsions. Diazepam or barbiturates.

Warning. Diazepam or barbiturates may aggravate respiratory depression (especially in children), hypotension, and coma. However, barbiturates should not be used if drugs that inhibit monoamine oxidase have also been taken by the patient either in overdosage or in recent therapy (within one week).

Surveillance. Respiration, cardiac function (ECG monitoring), blood pressure, body temperature, pupillary reflexes, and kidney and bladder function should be monitored for several days.

Treatment of Blood Count Abnormalities. If evidence of significant bone marrow depression develops, the following recommendations are suggested: (1) stop the drug, (2) perform daily CBC, platelet and reticulocyte counts, (3) do a bone marrow aspiration and trephine biopsy immediately and repeat with sufficient frequency to monitor recovery.

Special periodic studies might be helpful as follows: (1) white cell and platelet antibodies, (2) ^{59}Fe—ferrokinetic studies, (3) peripheral blood cell typing, (4) cytogenetic studies on marrow and peripheral blood, (5) bone marrow culture studies for colony-forming units, (6) hemoglobin electrophoresis for A_2 and F hemoglobin, and (7) serum folic acid and B_{12} levels.

A fully developed aplastic anemia will require appropriate, intensive monitoring and therapy, for which specialized consultation should be sought.

DOSAGE AND ADMINISTRATION

Monitoring of blood levels has increased the efficacy and safety of anticonvulsants (see PRECAUTIONS, Laboratory Tests). Dosage should be adjusted to the needs of the individual patient. A low initial daily dosage with a gradual increase is advised. As soon as adequate control is achieved, the dosage may be reduced very gradually to the minimum effective level. Tablets should be taken with meals.

Epilepsy (see INDICATIONS AND USAGE)

Adults and children over 12 years of age—Initial: 200 mg b.i.d. Increase at weekly intervals by adding up to 200 mg per day using a t.i.d. or q.i.d. regimen until the best response is obtained. Dosage should generally not exceed 1000 mg daily in children 12 to 15 years of age, and 1200 mg daily in patients above 15 years of age. Doses up to 1600 mg daily have been used in adults in rare instances. ***Maintenance:*** Adjust dosage to the minimum effective level, usually 800-1200 mg daily.

Children 6-12 years of age—Initial: 100 mg b.i.d. Increase at weekly intervals by adding 100 mg per day using a t.i.d. or q.i.d. regimen until the best response is obtained. Dosage should generally not exceed 1000 mg. ***Maintenance:*** Adjust dosage to the minimum effective level, usually 400-800 mg daily.

Combination Therapy: Tegretol may be used alone or with other anticonvulsants. When added to existing anticonvulsant therapy, the drug should be added gradually while the other anticonvulsants are maintained or gradually decreased, except phenytoin, which may have to be increased (see PRECAUTIONS, Drug Interactions and Pregnancy Category C).

Trigeminal Neuralgia (see INDICATIONS AND USAGE)

Initial: 100 mg b.i.d. on the first day for a total daily dose of 200 mg. This daily dose may be increased by up to 200 mg a day using increments of 100 mg every 12 hours only as needed to achieve freedom from pain. Do not exceed 1200 mg daily.

Maintenance: Control of pain can be maintained in most patients with 400 mg to 800 mg daily. However, some patients may be maintained on as little as 200 mg daily, while others may require as much as 1200 mg daily. At least once every 3 months throughout the treatment period, attempts should be made to reduce the dose to the minimum effective level or even to discontinue the drug.

HOW SUPPLIED

Chewable Tablets 100 mg—round, red-speckled, pink, single-scored (imprinted Tegretol on one side and 52 twice on the scored side)

Bottles of 100	NDC 0028-0052-01
Unit Dose (blister pack)	
Box of 100	
(strips of 10)	NDC 0028-0052-61

Tablets 200 mg—capsule-shaped, pink, single-scored (imprinted Tegretol on one side and 27 twice on the scored side)

Bottles of 100	NDC 0028-0027-01
Bottles of 1000	NDC 0028-0027-10
Gy-Pak®—One Unit	
12 bottles—100 tablets each	NDC 0028-0027-65
Unit Dose (blister pack)	
Box of 100	
(strips of 10)	NDC 0028-0027-61

Samples, when available, are identified by the word *SAMPLE* appearing on each tablet.

Protect from moisture.

Dispense in tight container (USP).

Also available as: Tegretol suspension 100 mg/5 ml, in 450 ml bottles.

Printed in U.S.A. C90-34 (Rev. 6/90)

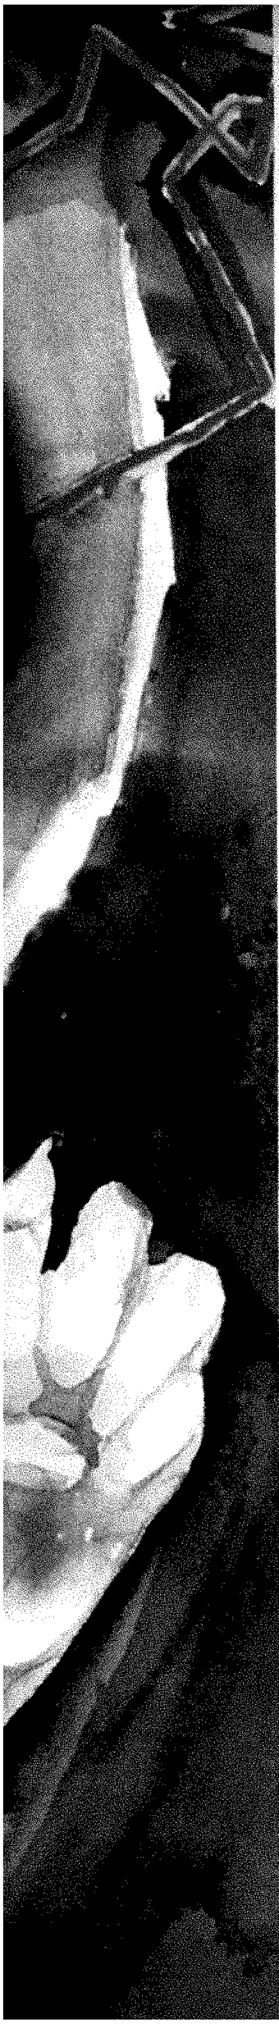
Calendar

CALENDAR OF MEETINGS

1991		
March	7-9	"Recent Advances in Geriatric Medicine, New Treatment Options for Old Problems," The Pan Pacific Hotel, San Diego, Calif. Contact Cass Jones, Professional Conference Management Inc, 7916 Convoy Ct, San Diego, CA 92111; (619) 565-9921.
	14-16	"Brain Chemistry and Behavior: Advances in Positron Emission Tomography and Single Photon Emission Tomography Imaging," Baltimore, Md. Contact Patty Campbell, Program Coordinator, The Johns Hopkins Medical Institutions, Office of Continuing Education, 720 Rutland Ave, Baltimore, MD 21205; (301) 955-3839.
	16-20	Fifth Annual Magnetic Resonance Imaging Conference, Marriott's Camelback Inn, Scottsdale, Ariz. Contact Kevin King, Education Coordinator, Radiologic Education Center, St Joseph's Hospital and Medical Center, 350 W Thomas Rd, Phoenix, AZ 85013; (602) 285-3956.
	17-21	The Eighth Conference of the Southeast European Society for Neurology and Psychiatry, Jerusalem, Israel. Contact Shaul Feldman, MD, PO Box 50006, Tel Aviv 61500, Israel.
	17-23	24th Latin American Congress of Neurosurgery, Miami, Fla. Contact Sergio Gonzalez-Arias, MD, 8950 N Kendall Dr, Suite 406, Miami, FL 33176; (305) 271-6159.
	18-20	"Spectrum of Developmental Disabilities: Cerebral Palsy: Issues of Early Detection and Intervention," The Johns Hopkins Medical Institutions, Baltimore, Md. Contact Program Coordinator, The Johns Hopkins Medical Institutions, Office of Continuing Education, Turner Bldg, 720 Rutland Ave, Baltimore, MD 21205; (301) 955-2959.
	21-33	"Recent Advances in Neurology and Neurosurgery," Scottsdale, Ariz. Contact Toby A. Jardine, Manager, Administration, Barrow Neurological Institute, 350 W Thomas Rd, Phoenix, AZ 85013; (602) 285-3178.
	23-24	Cervical and Lumbar Spine: State of the Art '91, Hyatt Regency Embarcadero, San Francisco, Calif. Contact the San Francisco Spine Institute, 1850 Sullivan Ave, Suite 140, Daly City, CA 94015; (415) 991-6761.
April	6	"Child Neuropsychology: Cognitive Development and Disorder." New York (NY) University Medical Center. Contact Karen Webb, PhD, New York Neuropsychology Group, Mount Sinai Medical Center, 19 E 98th St, Box 1228, New York, NY 10029; (212) 241-6148.
	10-11	The Second Annual Postgraduate Electromyography Review Course, Iowa City, Iowa. Contact Deborah L. Hatz, Program Coordinator, University of Iowa College of Medicine, Iowa City, IA 52242; (319) 335-8598.
	21-27	43rd Annual Meeting of the American Academy of Neurology, Hynes Convention Center, Boston, Mass. Contact American Academy of Neurology, 2221 University Ave SE, Suite 335, Minneapolis, MN 55414; (612) 623-8115.
	22	The Annual Meeting of the World Federation of Neurology Research Group on Neuroepidemiology, Boston, Mass. Contact Gustavo C. Román, Chief, Neuroepidemiology Branch, Federal Building, Room 714, 7550 Wisconsin Ave, National Institutes of Health, Bethesda, MD 20892; (301) 496-1714.
	27-28	1991 Neuroradiology Review Course, Oak Brook (Ill) Hills Hotel and Conference Center. Contact Continuing Medical Education, Loyola University Stritch School of Medicine, 2160 S First Ave, Maywood, IL 60153; (708) 216-3236.
	29-May 5	Advances in Internal Medicine, The Towsley Center, Ann Arbor, Mich. Contact Julie Jacobs, Office of Continuing Medical Education, G-1100 Towsley Center, Box 0201, University of Michigan Medical School, Ann Arbor, MI 48109-0201; (313) 763-1400.
May	6-8	"Neurotoxins and Their Potential Role in Neurodegeneration," Adams Mark Hotel, Philadelphia, Pa. Contact Marketing Department, The New York Academy of Sciences, 2 E 63rd St, New York, NY 10021; (212) 838-0230.
	7-10	Ecuadoran Society of Neurology, Quito, Ecuador. Contact Ecuadoran Society of Neurology, PO Box 2821, Quito, Ecuador.
	16-18	"Neurosurgical/Neurological Intensive Care: Update and Review," The Cleveland (Ohio) Clinic Foundation. Contact The Cleveland Clinic Foundation, Department of Continuing Education, 9500 Euclid Ave, Room TT-31, Cleveland, OH 44195-5241; 1-800-762-8173.
	17-18	"Pediatric Neurology for the '90's," Wilmington, Del. Contact Jeanne Cole, Continuing Medical Education Office, Alfred I. duPont Institute, 1600 Rockland Rd, Wilmington, DE 19899; (302) 651-6753.
	27-29	New Frontiers on Acute Ischemic Stroke-An Update, Rome, Italy. Contact Stroke Secretariat, Via Bertolini, 26/B, 00197 Rome, Italy.
	30-June 1	International Conference on Stroke, Geneva, Switzerland. Contact N. M. Bornstein, MD, International Conference on Stroke, c/o Kuoni Travel Ltd, 7 Rue de Berne, CH-1211 Geneva, Switzerland.
June	1-6	The 15th International Symposium on Cerebral Blood Flow and Metabolism, James L. Knight International Center, Miami, Fla. Contact Ms Jenny Bernal, Conference Coordinator, Brain '91, University of Miami Conference Center, 400 SE Second Ave, Fourth Floor, Miami, FL 33131.
	2-6	Ninth International Congress of Electromyography, Jerusalem, Israel. Contact Dr Arieh N. Gilai, Convener, EMG-CN-IX Congress, PO Box 29334, Tel Aviv 61292, Israel.
	10-13	Twelfth Annual Child Neurology Postgraduate Course, Sonesta Beach Hotel, Key Biscayne, Fla. Contact Oscar Papazian, MD, Department of Neurology, Miami Children's Hospital, 3200 SW 60th Ct, Miami, FL 33155; (305) 662-8330.
	19-22	The 26th Annual Meeting of the Canadian Congress of Neurological Sciences, Halifax (Nova Scotia) Sheraton. Contact Permanent Secretariat, Canadian Congress of Neurological Sciences, 810-906 12th Ave SW, Calgary, Alberta, Canada T2R 1K7; (403) 229-9544.
	21-23	"Current Concepts in Child Neurology," Hyatt Islandia Hotel, San Diego, Calif. Contact Continuing Medical Education, Children's Hospital and Health Center, 8001 Frost St, San Diego, CA 92123; (619) 576-1700.

HEADACHE DESCRIBED

"Headache"—a personal interpretation of headache pain by John Crowley, a headache patient.



HEADACHE RELIEVED

Effectively treats the pain of muscle contraction headache as well as the anxiety and tension that magnify it

FIORINAL WITH CODEINE (III) CAPSULES

(Each capsule contains: codeine phosphate 30 mg [Warning: May be habit-forming]; butalbital 50 mg [Warning: May be habit-forming]; caffeine 40 mg; and aspirin 325 mg)

Potent relief of tension headache pain

Please see brief summary on following page.

SANDOZPHARMACEUTICALS
Corporation, E. Hanover, NJ 07936 (201) 503-7500

BRIEF SUMMARY: Please see package insert for full prescribing information.

FIORINAL® WITH CODEINE CIII CAPSULES

(Codeine phosphate USP, 30 mg [warning: may be habit forming], butalbital USP, 50 mg [warning: may be habit forming]; caffeine USP, 40 mg; aspirin USP, 325 mg)

CAUTION: Federal law prohibits dispensing without prescription.

CONTRAINDICATIONS: Fiorinal® with Codeine is contraindicated under the following conditions:

1. Hypersensitivity or intolerance to aspirin, caffeine, butalbital or codeine.
2. Patients with a hemorrhagic diathesis (e.g., hemophilia, hypoprothrombinemia, von Willebrand's disease, the thrombocytopenias, thrombasthenia and other ill-defined hereditary platelet dysfunctions, severe vitamin K deficiency and severe liver damage.)
3. Patients with the syndrome of nasal polyps, angioedema and bronchospastic reactivity to aspirin or other nonsteroidal anti-inflammatory drugs. Anaphylactoid reactions have occurred in such patients.
4. Peptic ulcer or other serious gastrointestinal lesions.
5. Patients with porphyria.

WARNINGS: Therapeutic doses of aspirin can cause anaphylactic shock and other severe allergic reactions. It should be ascertained if the patient is allergic to aspirin, although a specific history of allergy may be lacking.

Significant bleeding can result from aspirin therapy in patients with peptic ulcer or other gastrointestinal lesions, and in patients with bleeding disorders.

Aspirin administered pre-operatively may prolong the bleeding time.

In the presence of head injury or other intracranial lesions, the respiratory depressant effects of codeine and other narcotics may be markedly enhanced, as well as their capacity for elevating cerebrospinal fluid pressure. Narcotics also produce other CNS depressant effects, such as drowsiness, that may further obscure the clinical course of patients with head injuries.

Codeine or other narcotics may obscure signs on which to judge the diagnosis or clinical course of patients with acute abdominal conditions.

Butalbital and codeine are both habit-forming and potentially abusable. Consequently, the extended use of Fiorinal® with Codeine is not recommended.

Results from epidemiologic studies indicate an association between aspirin and Reye Syndrome. Caution should be used in administering this product to children, including teenagers, with chicken pox or flu.

PRECAUTIONS: General: Fiorinal® with Codeine should be prescribed with caution for certain special-risk patients such as the elderly or debilitated, and those with severe impairment of renal or hepatic function, coagulation disorders, or head injuries.

Aspirin should be used with caution in patients on anticoagulant therapy and in patients with underlying hemostatic defects.

Precautions should be taken when administering salicylates to persons with known allergies. Hypersensitivity to aspirin is particularly likely in patients with nasal polyps, and relatively common in those with asthma.

Information for Patients: Patients should be informed that Fiorinal® with Codeine contains aspirin and should not be taken by patients with an aspirin allergy.

Fiorinal® with Codeine may impair the mental and/or physical abilities required for performance of potentially hazardous tasks such as driving a car or operating machinery. Such tasks should be avoided while taking Fiorinal® with Codeine.

Alcohol and other CNS depressants may produce an additive CNS depression when taken with Fiorinal® with Codeine, and should be avoided.

Codeine and butalbital may be habit-forming. Patients should take the drug only for as long as it is prescribed, in the amounts prescribed, and no more frequently than prescribed.

Laboratory Tests: In patients with severe hepatic or renal disease, effects of therapy should be monitored with serial liver and/or renal function tests.

Drug Interactions: The CNS effects of butalbital may be enhanced by monoamine oxidase (MAO) inhibitors.

In patients receiving concomitant corticosteroids and chronic use of aspirin, withdrawal of corticosteroids may result in salicylism because corticosteroids enhance renal clearance of salicylates and their withdrawal is followed by return to normal rates of renal clearance.

Fiorinal® with Codeine may enhance the effects of:

1. Oral anticoagulants, causing bleeding by inhibiting prothrombin formation in the liver and displacing anticoagulants from plasma protein binding sites.
2. Oral antidiabetic agents and insulin, causing hypoglycemia by contributing an additive effect, if dosage of Fiorinal® with Codeine exceeds maximum recommended daily dosage.
3. 6-mercaptopurine and methotrexate, causing bone marrow toxicity and blood dyscrasias by displacing these drugs from secondary binding sites, and, in the case of methotrexate, also reducing its excretion.
4. Non-steroidal anti-inflammatory agents, increasing the risk of peptic ulceration and bleeding by contributing additive effects.
5. Other narcotic analgesics, alcohol, general anesthetics, tranquilizers such as chlordiazepoxide, sedative-hypnotics, or other CNS depressants, causing increased CNS depression.

Fiorinal® with Codeine may diminish the effects of: Uricosuric agents such as probenecid and sulfinpyrazone, reducing their effectiveness in the treatment of gout. Aspirin competes with these agents for protein binding sites.

Drug/Laboratory Test Interactions

Aspirin: Aspirin may interfere with the following laboratory determinations in blood: serum amylase, fasting blood glucose, cholesterol, protein, serum glutamic-oxalacetic transaminase (SGOT), uric acid, prothrombin time and bleeding time. Aspirin may interfere with the following laboratory determinations in urine: glucose, 5-hydroxyindoleacetic acid, Gerhardt ketone, vanillylmandelic acid (VMA), uric acid, diacetic acid, and spectrophotometric detection of barbiturates.

Codeine: Codeine may increase serum amylase levels.

Carcinogenesis, Mutagenesis, Impairment of Fertility: Adequate long-term studies have been conducted in mice and rats with aspirin, alone or in combination with other drugs, in which no evidence of carcinogenesis was seen. No adequate studies have been conducted in animals to determine whether aspirin has a potential for mutagenesis or impairment of fertility. No adequate studies have been conducted in animals to determine whether butalbital has a potential for carcinogenesis, mutagenesis, or impairment of fertility.

Usage in Pregnancy

Teratogenic Effects: Pregnancy Category C — Animal reproduction studies have not been conducted with Fiorinal® with Codeine. It is also not known whether Fiorinal® with Codeine can cause fetal harm when administered to a pregnant woman or can affect reproduction capacity. Fiorinal® with Codeine should be given to a pregnant woman only when clearly needed.

Nonteratogenic Effects: Although Fiorinal® with Codeine was not implicated in the birth defect, a female infant was born with lissencephaly, pachygyria and heterotopic gray matter. The infant was born 8 weeks prematurely to a woman who had taken an average of 90 Fiorinal® with Codeine capsules each month from the first few days of pregnancy. The child's development was mildly delayed and from one year of age she had partial simple motor seizures.

Withdrawal seizures were reported in a two-day-old male infant whose mother had taken a butalbital-containing drug during the last 2 months of pregnancy. Butalbital was found in the infant's serum. The infant was given phenobarbital 5mg/kg, which was tapered without further seizure or other withdrawal symptoms.

Studies of aspirin use in pregnant women have not shown that aspirin increases the risk of abnormalities when administered during the first trimester of pregnancy. In controlled studies involving 41,337 pregnant women and their offspring, there was no evidence that aspirin taken during pregnancy caused stillbirth, neonatal death or reduced birth weight. In controlled studies of 50,282 pregnant women and their offspring, aspirin administration in moderate and heavy doses during the first four lunar months of pregnancy showed no teratogenic effect.

Reproduction studies have been performed in rabbits and rats at doses up to 150 times the human dose and have revealed no evidence of impaired fertility or harm to the fetus due to codeine.

Therapeutic doses of aspirin in pregnant women close to term may cause bleeding in mother, fetus, or neonate. During the last 6 months of pregnancy, regular use of aspirin in high doses may prolong pregnancy and delivery.

Labor and Delivery: Ingestion of aspirin prior to delivery may prolong delivery or lead to bleeding in the mother or neonate. Use of codeine during labor may lead to respiratory depression in the neonate.

Nursing Mothers: Aspirin, caffeine, barbiturates and codeine are excreted in breast milk in small amounts, but the significance of their effects on nursing infants is not known. Because of potential for serious adverse reactions in nursing infants from Fiorinal® with Codeine, a decision should be made whether to discontinue nursing or to discontinue the drug, taking into account the importance of the drug to the mother.

Pediatric Use: Safety and effectiveness in children below the age of 12 have not been established.

ADVERSE REACTIONS: Commonly Observed: The most commonly reported adverse events associated with the use of Fiorinal® with Codeine and not reported at an equivalent incidence by placebo-treated patients were nausea and/or abdominal pain, drowsiness, and dizziness.

Associated with Treatment Discontinuation: Of the 382 patients treated with Fiorinal® with Codeine in controlled clinical trials, three (0.8%) discontinued treatment with Fiorinal® with Codeine because of adverse events. One patient each discontinued treatment for the following reasons: gastrointestinal upset; lightheadedness and heavy eyelids; and drowsiness and generalized tingling.

Incidence in Controlled Clinical Trials: The following table summarizes the incidence rates of the adverse events reported by at least 1% of the Fiorinal® with Codeine treated patients in controlled clinical trials comparing Fiorinal® with Codeine to placebo, and provides a comparison to the incidence rates reported by the placebo-treated patients.

The prescriber should be aware that these figures cannot be used to predict the incidence of side effects in the course of usual medical practice where patient characteristics and other factors differ from those that prevailed in the clinical trials. Similarly, the cited frequencies cannot be compared with figures obtained from other clinical investigations involving different treatments, uses, and investigators.

Adverse Events Reported by at Least 1% of Fiorinal® with Codeine Treated Patients During Placebo Controlled Clinical Trials

	Incidence Rate of Adverse Events	
Body System/ Adverse Event	Fiorinal®/Codeine (N = 382)	Placebo (N = 377)
Central Nervous		
Drowsiness	2.4%	0.5%
Dizziness/Lightheadedness	2.6%	0.5%
Intoxicated Feeling	1.0%	0%
Gastrointestinal		
Nausea/Abdominal Pain	3.7%	0.8%

Other Adverse Events Reported During Controlled Clinical Trials: The listing that follows represents the proportion of the 382 patients exposed to Fiorinal® with Codeine while participating in the controlled clinical trials who reported, on at least one occasion, an adverse event of the type cited. All reported adverse events, except those already presented in the previous table, are included. It is important to emphasize that, although the adverse events reported did occur while the patient was receiving Fiorinal® with Codeine, the adverse events were not necessarily caused by Fiorinal® with Codeine.

Adverse events are classified by body system and frequency. "Frequent" is defined as an adverse event which occurred in at least 1/100 (1%) of the patients; all adverse events listed in the previous table are frequent. "Infrequent" is defined as an adverse event that occurred in less than 1/100 patients but at least 1/1000 patients. All adverse events tabulated below are classified as infrequent.

Central Nervous: headache, shaky feeling, tingling, agitation, fainting, fatigue, heavy eyelids, high energy, hot spells, numbness, and sluggishness.

Autonomic Nervous: dry mouth and hyperhidrosis.

Gastrointestinal: vomiting, difficulty swallowing, and heartburn.

Cardiovascular: tachycardia.

Musculoskeletal: leg pain and muscle fatigue.

Genitourinary: diuresis.

Miscellaneous: pruritus, fever, earache, nasal congestion, and tinnitus.

Voluntary reports of adverse drug events, temporally associated with Fiorinal® with Codeine, that have been received since market introduction and that were not reported in clinical trials by the patients treated with Fiorinal® with Codeine, are listed below. Many or most of these events may have no causal relationship with the drug and are listed according to body system.

Central Nervous: Abuse, addiction, anxiety, depression, disorientation, hallucination, hyperactivity, insomnia, libido decrease, nervousness, neuropathy, psychosis, sedation, sexual activity increase, slurred speech, twitching, unconsciousness, vertigo.

Autonomic Nervous: epistaxis, flushing, miosis, salivation.

Gastrointestinal: anorexia, appetite increased, constipation, diarrhea, esophagitis, gastroenteritis, gastrointestinal spasm, hiccup, mouth burning, pyloric ulcer.

Cardiovascular: chest pain, hypotensive reaction, palpitations, syncope.

Skin: erythema, erythema multiforme, exfoliative dermatitis, hives, rash, toxic epidermal necrolysis.

Urinary: kidney impairment, urinary difficulty.

Miscellaneous: allergic reaction, anaphylactic shock, cholangiocarcinoma, drug interaction with erythromycin (stomach upset), edema.

The following adverse drug events may be borne in mind as potential effects of the components of Fiorinal® with Codeine. Potential effects of high dosage are listed in the *OVERDOSAGE* section of this insert.

Aspirin: occult blood loss, hemolytic anemia, iron deficiency anemia, gastric distress, heartburn, nausea, peptic ulcer, prolonged bleeding time, acute airway obstruction, renal toxicity when taken in high doses for prolonged periods, impaired urate excretion, hepatitis.

Caffeine: cardiac stimulation, irritability, tremor, dependence, nephrotoxicity, hyperglycemia.

Codeine: nausea, vomiting, drowsiness, lightheadedness, constipation, pruritus.

DRUG ABUSE AND DEPENDENCE: Fiorinal® with Codeine is controlled by the Drug Enforcement Administration and is classified under Schedule III.

Codeine: Codeine can produce drug dependence of the morphine type and, therefore, has the potential for being abused. Psychological dependence, physical dependence, and tolerance may develop upon repeated administration and it should be prescribed and administered with the same degree of caution appropriate to the use of other oral narcotic medications.

Butalbital: *Barbiturates may be habit forming:* Tolerance, psychological dependence, and physical dependence may occur especially following prolonged use of high doses of barbiturates. The average daily dose for the barbiturate addict is usually about 1,500 mg. As tolerance to barbiturates develops, the amount needed to maintain the same level of intoxication increases; tolerance to a fatal dosage, however, does not increase more than two-fold. As this occurs, the margin between an intoxication dosage and fatal dosage becomes smaller. The lethal dose of a barbiturate is far less if alcohol is also ingested. Major withdrawal symptoms (convulsions and delirium) may occur within 16 hours and last up to 5 days after abrupt cessation of these drugs. Intensity of withdrawal symptoms gradually declines over a period of approximately 15 days. Treatment of barbiturate dependence consists of cautious and gradual withdrawal of the drug. Barbiturate-dependent patients can be withdrawn by using a number of different withdrawal regimens. One method involves initiating treatment at the patient's regular dosage level and gradually decreasing the daily dosage as tolerated by the patient.

OVERDOSAGE: The toxic effects of acute overdosage of Fiorinal® with Codeine capsules are attributable mainly to the barbiturate and codeine components, and, to a lesser extent, aspirin. Because toxic effects of caffeine occur in very high dosages only, the possibility of significant caffeine toxicity from Fiorinal® with Codeine overdosage is unlikely.

Signs and Symptoms: Symptoms attributable to *acute barbiturate poisoning* include drowsiness, confusion, and coma; respiratory depression; hypotension; shock. Symptoms attributable to *acute aspirin poisoning* include hyperpnea; acid-base disturbances with development of metabolic acidosis; vomiting and abdominal pain; tinnitus, hyperthermia; hypoprothrombinemia; restlessness; delirium; convulsions. *Acute caffeine poisoning* may cause insomnia, restlessness, tremor, and delirium; tachycardia and extrasystoles. Symptoms of *acute codeine poisoning* include the triad of: pinpoint pupils, marked depression of respiration, and loss of consciousness. Convulsions may occur.

Treatment: The following paragraphs describe one approach to the treatment of overdose with Fiorinal® with Codeine. However, because strategies for the management of an overdose continually evolve, consultation with a regional poison control center is strongly encouraged.

Treatment consists primarily of management of barbiturate intoxication, reversal of the effects of codeine, and the correction of the acid-base imbalance due to salicylism. Vomiting should be induced mechanically or with emetics in the conscious patient. Gastric lavage may be used if the pharyngeal and laryngeal reflexes are present and if less than 4 hours have elapsed since ingestion. A cuffed endotracheal tube should be inserted before gastric lavage of the unconscious patient and when necessary to provide assisted respiration. Diuresis, alkalinization of the urine, and correction of electrolyte disturbances should be accomplished through administration of intravenous fluids such as 1% sodium bicarbonate and 5% dextrose in water.

Meticulous attention should be given to maintaining adequate pulmonary ventilation. Correction of hypotension may require the administration of levarterenol bitartrate or phenylephrine hydrochloride by intravenous infusion. In severe cases of intoxication, peritoneal dialysis, hemodialysis, or exchange transfusion may be lifesaving. Hypoprothrombinemia should be treated with vitamin K, intravenously.

Methemoglobinemia over 30% should be treated with methylene blue by slow intravenous administration.

Naloxone, a narcotic antagonist, can reverse respiratory depression and coma associated with opioid overdose. Typically, a dose of 0.4 mg to 2 mg is given parenterally and may be repeated if an adequate response is not achieved. Since the duration of action of codeine may exceed that of the antagonist, the patient should be kept under continued surveillance and repeated doses of the antagonist should be administered as needed to maintain adequate respiration. A narcotic antagonist should not be administered in the absence of clinically significant respiratory or cardiovascular depression.

Toxic and Lethal Doses:

Butalbital: toxic dose 1.0 g (adult); lethal dose 2.0-5.0 g
Aspirin: toxic blood level greater than 30 mg/100 mL; lethal dose 10-30 g (adult)
Caffeine: toxic dose greater than 1.0 g; lethal dose unknown
Codeine: lethal dose 0.5-1.0 g (adult)

[NOVEMBER 1, 1990 FWC-Z26]

Instructions for Authors

Send manuscripts by first-class mail to the Chief Editor, Robert J. Joynt, MD, PhD, University of Rochester School of Medicine and Dentistry, 601 Elmwood Ave, Rochester, NY 14642. Manuscripts are received with the understanding that they are not under simultaneous consideration by another publication. Accepted manuscripts become the permanent property of the ARCHIVES and may not be published elsewhere without permission from the publisher (AMA).

Cover Letter.—Designate one author as correspondent and provide a complete address and telephone number.

In the cover letter include (1) statement on authorship responsibility, (2) statement on financial disclosure, and (3) one of the two following statements on copyright *or* federal employment. Each of these three statements must be signed by *all* authors.

1. Authorship Responsibility.—"I certify that I have participated sufficiently in the conception and design of this work and the analysis of the data (when applicable), as well as the writing of this manuscript, to take public responsibility for it. I believe the manuscript represents valid work. I have reviewed the final version of the manuscript and approve it for publication. Neither this manuscript nor one with substantially similar content under my authorship has been published or is being considered for publication elsewhere, except as described in an attachment. Furthermore, I attest that I shall produce the data upon which the manuscript is based for examination by the editors or their assignees if requested."

2. Financial Disclosure.—"I certify that affiliations (if any) with or involvement in any organization or entity with a direct financial interest in the subject matter or materials discussed in the manuscript (eg, employment, consultancies, stock ownership, honoraria, expert testimony) are disclosed below."

Research or project support should be listed in an acknowledgement.

3a. Copyright Transfer.—"In consideration of the action of the American Medical Association (AMA) in reviewing and editing this submission, the author(s) undersigned hereby transfer(s) assign(s), or otherwise convey(s) all copyright ownership to the AMA in the event that such work is published by the AMA."

3b. Federal Employment.—"I was an employee of the US federal government when this work was investigated and prepared for publication; therefore, it is not protected by the Copyright Act and there is no copyright of which the ownership can be transferred."

We regret that transmittal letters not containing the preceding language signed by all authors of the submission will necessitate delay in review of the manuscript.

Editing.—All accepted manuscripts are subject to copy editing. The author will receive an edited typescript rather than galley proofs for approval. The author is responsible for all statements in his work, including changes made by the copy editor.

Order reprints at the time the typescript is returned after editorial processing. Specify address to which requests for reprints should be sent.

Manuscript Preparation.—Submit three high-quality copies of the entire manuscript. The copies will not be returned. The authors should keep the original manuscript for submission if accepted. The original manuscript (including references, legends, and tables) must be typed double-spaced on 21.6 × 27.9-cm 8½ × 11-in), heavy-duty white bond paper. Ample margins of at least 2.5 cm (1 in) should be provided. **If a word processor is used, do not justify right-hand margins.**

Refer to patients by number (or, in anecdotal reports, by fictitious given names). Real names or initials should not be used in the text, tables, or illustrations.

Titles.—Titles should be short, specific, and clear. They should not exceed 42 characters per line, including punctuation and spaces, and be limited to two lines, if possible. The title page should include the full names and academic affiliations of all authors, and the address to which requests for reprints should be sent.

Style of Writing.—The style of writing should conform to acceptable English usage and syntax. Slang, medical jargon, obscure abbreviations, and abbreviated phrasing are to be avoided.

Informed Consent.—Manuscripts reporting the results of experimental investigations of human subjects must include a statement to the effect that informed consent was obtained after the nature of the procedure(s) had been fully explained.

Abstract.—Provide an abstract (135-word maximum) of the article, including statements of the problem, method of study, results, and conclusions. The abstract replaces the summary.

References.—List references in consecutive numerical order (not alphabetically). Once a reference is cited, all subsequent citations should be to the original number. All references must be cited in the text or tables. Unpublished data and personal communications should not be listed as references. References to journal articles should include (1) author(s) (list all authors and/or editors up to six; if more than six, list the first three and "et al"), (2) title, (3) journal name (as abbreviated in *Index Medicus*), (4) year, (5) volume number, and (6) inclusive page numbers, in that order. References to books should include (1) author(s) (list all authors and/or editors up to six; if more than six, list the first three and "et al"), (2) chapter title (if any), (3) editor (if any), (4) title of book, (5) city of publication, (6) publisher, and (7) year. Volume and edition numbers, specific pages, and name of translator should be included when appropriate. **The author is responsible for the accuracy and completeness of the references and for their correct text citation.**

SI Units.—Use Système International (SI) measurements throughout the manuscript. (See June 1986 issue of the ARCHIVES.)

Illustrations.—The illustrations originally submitted will not be returned. High-quality copies may be used. Original illustrations should be kept by the author for submission if the manuscript is accepted. Use only those illustrations that clarify and augment the text. If accepted, submit illustrations in triplicate, unmounted and untrimmed. Do not send original artwork. Send high-contrast glossy prints (not photocopies). Figure number, name of senior author, and arrow indicating "top" should be typed on a gummed label and affixed to the back of each illustration. All lettering must be legible after reduction to column size. Artwork submitted for publication may be relettered to achieve uniformity of lettering style throughout the journal. Magnification and stain should be provided when pertinent. Illustrations should preferably be in a proportion of 12.7 × 7.3 cm (5 × 7 in).

Template lettering or preset type is preferred to hand-lettered labels. If halftone artwork with labels is submitted, affix type and leaders to a clear acetate overlay registered to the base drawing. Labels and leaders should be applied directly to the drawing board surface if the artwork consists only of line ink technique.

Illustrations in full color are accepted for publication if the editors believe that color will add significantly to the published manuscript. The ARCHIVES will pay part of the expense of reproduction and printing color illustrations, the remainder to be borne by the author or his sponsor. After deducting the ARCHIVES' contribution, the author's share is $400 for up to six square-finished illustrations that can be arranged on a one-page layout. Any additional illustrations or special effects will be billed to the author at cost. Positive color transparencies (35 mm preferred) must be submitted for an evaluation. Do not send color prints unless accompanied by original transparencies. All transparencies should be carefully packed and sent with the manuscript.

Legends.—Legends should be typed double-spaced, beginning on a separate sheet of paper. Length should be limited to a maximum of 40 words.

Photographic Consents.—A letter of consent must accompany all photographs of patients in which a possibility of identification exists. It is not sufficient to cover the eyes to mask identity.

Acknowledgments.—Illustrations from other publications must be acknowledged. Include the following when applicable: author(s), title of article, title of journal or book, volume number, page(s), month, and year. The publisher's permission to reprint should be submitted to the ARCHIVES after the manuscript has been formally accepted.

Statistical Review.—Manuscripts containing statistical evaluations should include the name and affiliation of the statistical reviewer.

Tables.—Each table should be typed double-spaced, including all headings, on a separate sheet of 21.6 × 27.9-cm (8½ × 11-in) paper. Do not use larger size paper. If a table must be continued, use a second sheet and repeat all heads and stubs. Each table must have a title.

Letters to the Editor

Letters to the editor should be submitted as an original and two duplicates. They should be typewritten double-spaced on plain bond paper; they will be subject to editing. If they are prepared on a word processor, do not justify the right margin. A copyright transmittal letter signed by all authors must accompany this (see "Instructions for Authors").

Brain-Stem Tuberculoma

To the Editor.—It is with interest that we read the article entitled "Brain-Stem Tuberculoma, An Analysis of 11 Patients" written by Talamás et al[1] that appeared in the May 1989 issue of the ARCHIVES.

It is a well-known fact that the diagnosis of central nervous system tuberculosis is a very difficult one, especially because of the wide variety of clinical presentation of this disease. Recently, the development of neuroimaging methods and several immunological techniques, including the enzyme-linked immunosorbent assay method, for tuberculous antigens, has increased the accuracy of this diagnosis. However, there are still some cases in which the definitive diagnosis has to be made through brain or meningeal biopsy specimens.

Of the 11 cases presented in this article, only in one patient was the diagnosis proved through histological findings, and in the remaining 10 patients, "it was supported or inferred through clinical presentation, cerebrospinal fluid analysis, computed tomography, or magnetic resonance imaging, and response to antituberculous therapy." The clinical manifestations of central nervous system tuberculosis are variable and unspecific, and they are very difficult to differentiate from tumors, fungal and parasitic disease, or vasculitides of the brain stem. The cerebrospinal fluid analysis in these cases did not show specific changes (hyperproteinorrachia in four cases and mild pleocytosis in three patients). The glucose levels and immunological test results were not reported. At the present time, there are new techniques for the detection of *Mycobacterium tuberculosis*-specific markers in the cerebrospinal fluid, such as frequency-pulsed electron-capture gas-liquid chromatography (specificity, 90%); enzyme-linked immunosorbent assay (specificity, 95%); latex particle agglutination (specificity, 99%); and serum enzyme-linked immunosorbent assay (specificity, 94% to 100%),[2] which could have been performed, at least in the latter cases reported by the authors. We agree with the author's discussion about the value of computed tomographic findings in the diagnosis of central nervous system tuberculosis, but Fig 4, which apparently shows improvement of the brain-stem lesion due to antituberculous therapy, cannot be postulated as such because the follow-up computed tomographic scan shows a different axial level. In regard to magnetic resonance imaging findings, the T_2-weighted image in Fig 1 shows a high-intensity signal lesion involving most of the brain stem and part of the cerebellum, which, according to our experience, may represent meningoencephalovasculitis,[3] infiltrating glioma, metastatic tumor, or fungal infection. We have a similar case (Fig 1) which corresponded on postmortem examination to a tuberculosis meningoencephalovasculitis, which simulated, even at gross examination, an infiltrating brain-stem glioma (Fig 2).

The authors based the diagnosis of brain-stem tuberculoma in most cases on the fact of the response to antituberculous therapy, but this assumption cannot be supported in cases Nos. 6 and 10.

We want to emphasize that brain-stem tuberculoma has to be differentiated from other pathologic findings of this neuroanatomical region, including the form of central nervous system tuberculosis called *tuberculous meningoencephalovasculitis*, which can simulate brain-stem infiltrating glioma, such as was demonstrated in our case that was presented elsewhere[3] (Figs 1 and 2).

In summary, we conclude that the diagnosis of brain-stem tuberculoma should not be supported mainly through the response to antituberculous therapy, but only with the rational use of other diagnostic methods

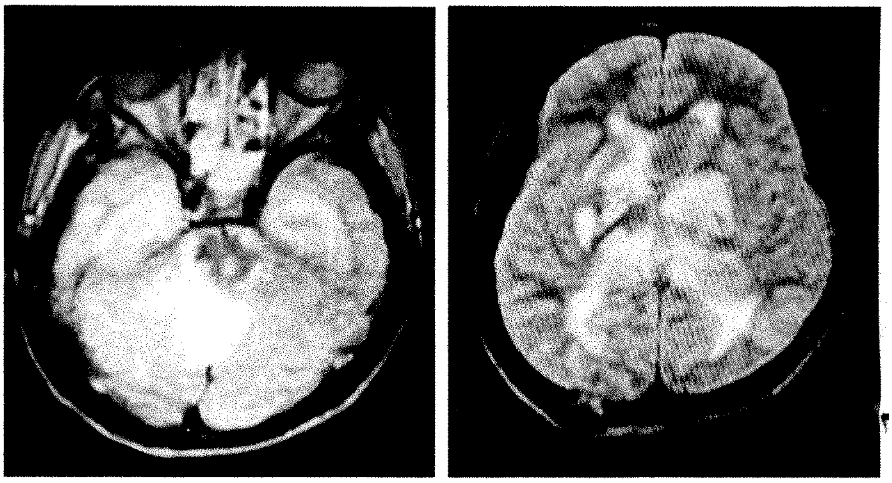

Fig 1.—Left, High-intensity signal in the brain stem and part of the cerebellum; an irregular hypointense area is observed in the center of the brain stem (80/2000). Right, Multiple high-intensity signal areas in the periventricular region and basal ganglia (80/2000).

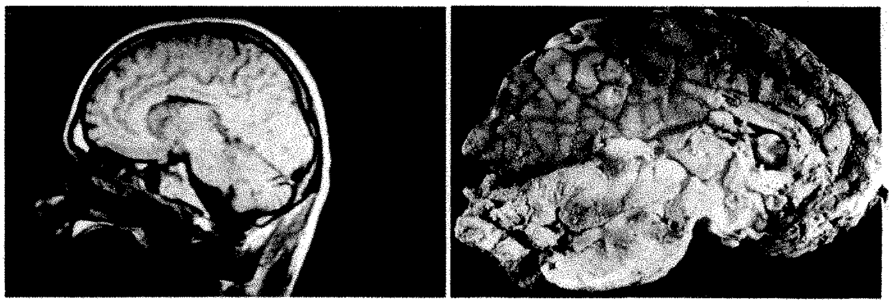
Fig 2.—Left, Isointense lesion involving the brain-stem simulating an infiltrating glioma (28/500). Right, Sagittal cut of the brain showing an infiltrating lesion in the brain stem.



such as immunological tests in cerebrospinal fluid (with well-known specificity), as well as computed tomography and magnetic resonance imaging,[4,5] and, in selected cases, through neuropathological examination.

Brain-Stem Tuberculomas

To the Editor.—It was with great interest that I read the article on brain-stem tuberculomas by Talamas et al.[1] I am concerned about the diagnosis in patients 3 and 8. In both these patients, there were single, isolated brain-stem masses and neither had evidence of systemic tuberculosis. Diagnosis in these patients was based either on the disappearance of the lesion in the computed tomographic scan (patient 3) or clinical improvement (patient 8), following antituberculous therapy. Our experience shows that these criteria are not foolproof. For a number of years single, small, enhancing lesions noted on computed tomography in Indian patients with seizures were diagnosed as tuberculomas and treated accordingly on the basis of the above criteria (ie, disappearance on the scan or clinical improvement with antituberculous therapy).[2] After excision biopsy specimens (using computed tomographic-guided stereotaxic localization) were obtained in 15 consecutive patients, we proved that, in nearly all cases, these lesions were caused by cysticercosis and needed no specific therapy.[3] Thus it is important to consider other inflammatory or demyelinating disorders in such cases, and one cannot be categorical in making a diagnosis of a tuberculous lesion. Second, it is rare for tuberculomas to occur as isolated single brain-stem masses (ie, without any other coexistent brain masses) in the absence of active systemic tuberculosis or tuberculous meningitis. In our center, patients with tuberculomas are still seen quite often. However, in a consecutive series of eight patients with isolated brain-stem masses, who underwent computed tomographic-guided stereotaxic biopsy, there were no tuberculomas. This underlines the fact that, even in endemic areas such as ours, a tuberculoma only rarely presents as an isolated brain-stem mass. Third, exposure to tuberculosis alone (patient 3) cannot be considered as adequate evidence to support the diagnosis of a tuberculoma, because there is a high incidence of such an exposure in the general patient population in developing countries.

A confident diagnosis of a brain-stem tuberculoma without histologic proof can only be considered in patients with active systemic tuberculosis or tuberculous meningitis, and more so if there are multiple lesions involving other areas of the brain. In all other cases a histologic diagnosis should be obtained, as empirical antituberculous therapy may delay appropriate therapy. In the case of isolated brain-stem masses computed tomographic-guided stereotaxic biopsy would be the ideal procedure.

Cardiac Sources of Cerebral Embolism

To the Editor.—We read with interest the second report on brain embolism by the Task Force.[1] In reviewing their first article,[2] they estimated that the incidence of stroke due to cardiogenic embolism should be around 15%, ranging between 6% and 23%, of all ischemic strokes. When discussing heart pathologies, they established that nonvalvular atrial fibrillation, ischemic heart disease, rheumatic heart disease, and prosthetic cardiac valves account for the majority of cardioembolic stroke and considered that nonischemic dilated cardiomyopathies were a less common cardiac cause of embolism. These data have been obtained from studies published in the English-language literature and encompass reports originated mainly in the Northern Hemisphere. However, it is reasonable to assume that other areas in the world may have a different incidence of heart disease, causing embolic brain damage, due to the presence of regional predisposing factors.

Recently, we reviewed our own data consisting of 367 patients who were assessed at our stroke clinic between 1983 and 1989. All of these patients had a diagnosis of ischemic stroke based on clinical findings and brain computed tomographic scan. The criteria employed for the diagnosis of cardioembolic stroke included the following: (1) sudden onset and maximal neurological focal deficit from the very beginning of the episode, (2) brain computed tomographic scan showing an ischemic lesion, or features consistent with cardioembolic stroke (ie, hemorrhagic infarct or multiple cortical infarcts in different vascular territories (images consistent with lacunar strokes were excluded), (3) M-mode and bidimensional echocardiography, or cardiac catheterization showing the heart as the source of the emboli, and (4) absence of stenotic-occlusive cerebrovascular disease by cerebral angiography, when performed in the group of patients with probable atherosclerotic vascular disease.

Forty-seven patients (12.8%) filled the criteria for being considered affected by brain embolism of cardiac origin. The group was composed of 21 women and 26 men. Their ages ranged between 26 and 79 years (mean, 54 years). The emboligenic heart disorders found included the following: (1) nonvalvular atrial fibrillation in 13 patients (27.6%), (2) rheumatic heart disease in 10 patients (21.2%), (3) nonischemic dilated cardiomyopathy in eight patients (17%), and (4) ischemic heart disease in seven patients (14.9%). The remaining nine patients (19.7%) had other conditions; namely, bacterial endocarditis (three patients), mitral valve prolapse (two patients), nondilated cardiomyopathy (two patients), prosthetic cardiac valve (one patient), and congenital heart malformation (one patient). From the eight patients who had nonischemic dilated cardiomyopathy, five (62%) had cardiac involvement due to Chagas' disease.

Taken together, our figures show that, although they are well in line with the current literature,[1] nonischemic dilated cardiomyopathy is one of the main causes of ischemic stroke due to cardiac embolism in our community. Most likely, this reflects the presence of regional factors, Chagas' disease in the present series, which may not play any role in other geographic areas. Chagas' disease is an endemic parasitic illness in our country (and in all Latin America[3]), leading to involvement of the heart yielding a nonischemic dilated cardiomyopathy that, in turn, may be the cause of ischemic embolic stroke.[4]

Magnetic Resonance Evaluation of the Midbrain in Parkinson's Disease

To the Editor.—We commend the investigation by Huber et al[1] of midbrain pars compacta size in Parkinson's disease (PD) using magnetic resonance imaging (MRI). The authors have stimulated interest in an important area of new research, namely the use of MRI to correlate anatomic finding in vivo with clinical disease. Their detailed attention to the MRI methodology adds credence to their findings. However, methodological issues related to the composition and selection of the control group need to be considered carefully and the design of the present study illustrates some of the difficulties frequently encountered.

The authors have not reported the range and mean (±SD) age for the mild and moderate/severe PD groups as well as the standard deviation for age in the control and PD groups. We are concerned that the group of mild PD patients may have been significantly younger than the control subjects. Age may have an effect on pars compacta size independent of the measured clinical variable (ie, severity of PD). McGeer et al[2] have reported a significant age-related loss of substantia nigra neurons between the ages of 20 and 80 years. We have recently documented in 36 normal volunteer subjects that the cross-sectional area of the midbrain (measured on sagittal MRI) declines significantly between the age of 26 and 79 years, and that this decline is particularly prominent in subjects over 60 years (submitted for publication). If the mild PD group was younger than the control group, it would be of interest to know whether age effects obscured potential differences in pars compacta size.

Second, the authors have not mentioned the male/female composition of the PD and control groups (all control subjects were spouses of patients). The higher prevalence of PD in males may have resulted in a higher number of female control subjects. It is of interest that, in our study (referred to above), the age-related decline in midbrain area was more prominent in men than in women, though we did not measure pars compacta size. In addition, it is not known whether the greater age-related mortality from PD in males reflects a greater susceptibility to pars compacta degeneration in male subjects.

It is of interest that the first MRI study of pars compacta size in PD[3] found very little overlap between control and PD groups, whereas the two subsequent studies[1,4] have found a much greater overlap. Differences in control groups and a wide variation in pars compacta size in normal subjects may partly explain these discrepancies. In our study, midbrain dimensions varied almost threefold in normal volunteer subjects between the ages of 26 and 79.

These studies highlight the importance of strictly controlling for age and gender in morphometric studies of the midbrain, though the logistics of volunteer recruitment often preclude such an ideal study design. As the authors point out, inadequate normative data, as well as an apparent overlap between PD and control values, precludes the use of MRI criteria (such as pars compacta size or asymmetry) as reliable diagnostic markers for PD at present. Continued MRI studies of brain structural changes in normal aging and in PD remain essential to resolve these issues.

In Reply.—We appreciate the useful comments provided by Doraiswamy and associates. While we tried to make our report as methodologically sound as possible, they correctly point out that we did not fully evaluate the potential effects of age. The age (mean ± SD) for the mild Parkinson's disease group (61.4 ± 8.7), the moderate/severe Parkinson's disease group (66.1 ± 8.0), and the normal control subjects (68.4 ± 4.0) produced a difference among groups that just failed to reach statistical significance, $F(2,51) = 2.99$, $P < .06$. However, the relatively young age of the mild Parkinson's disease group does warrant an examination of the potential effects of age on our results. We performed an analysis of covariance, with age as the covariate, on both the average width and width difference on the first echo images. There was a significant difference among the groups for width average, $F(3,50) = 3.64$, $P < .02$, and width difference, $F(3,50) = 5.53$, $P < .002$. Post hoc comparisons indicated a significantly narrower average width in the moderate/severe Parkinson's disease group, and a greater left-to-right width difference in the mild Parkinson's disease group. This pattern is identical to our original analyses and suggests that age had no secondary effect on our results. The male/female composition of the mild Parkinson's disease group (11/5), the moderate/severe Parkinson's disease group (19/9), and the control group (5/5) was not significantly different, $\chi^2 = 1.2$. Thus, it is unlikely that sex had an effect on our results.

At the present time, magnetic resonance imaging measures do not provide reliable diagnostic information for the individual patient due to qualitative overlap with normal control subjects. While asymmetry in width does appear to be most evident quantitatively in the early stages of Parkinson's disease, advances with further research will depend on adherence to strict methodology. The issues raised by Doraiswamy and associates are important in this regard.

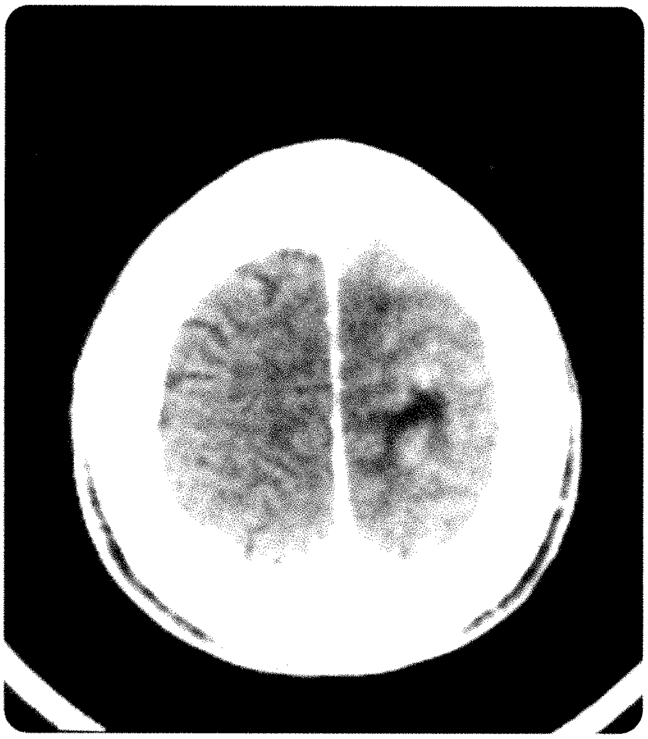
THE DECISION
IS YOURS.

COMPARE.

THE CASE: A 40-year-old man presented with a 2-month history of involuntary muscle contractions of the right arm and mild weakness of the left leg.

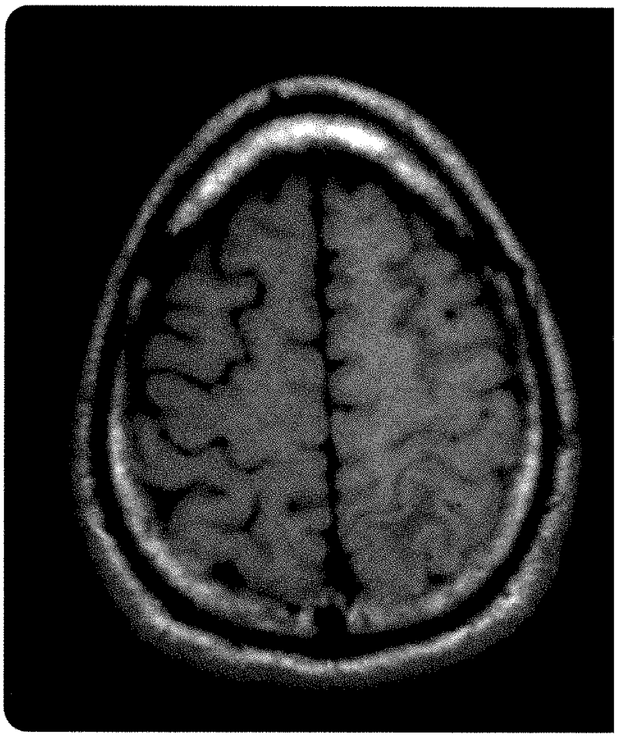
First there was CT.



Contrast CT scan shows an area of low attenuation in the left parietal lobe. A questionable focus of contrast is seen, but this may represent cerebral cortex.

Images courtesy of Michael R. Ross, MD, Stanford University Medical Center, Stanford, California

Then MRI.



T1-weighted (TR 800/TE 20) unenhanced MR image, obtained with a 1.5-T imager, shows subcortical hypointensity in the lef posterior parietal lobe. The surrounding sulci appear to be compressed, but a mass is not clearly appreciated.

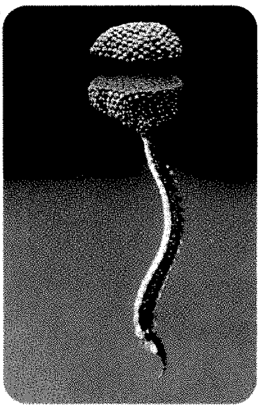
NOTHING LOCATES LESIONS BETTER

Please see brief summary of prescribing information for
MAGNEVIST® injection on last page of this advertisement.



Well tolerated[1] In clinical trials, the most common adverse reactions reported were headache (8.7%) and injection-site coldness/localized coldness (4.8%). The majority of headaches were transient and of mild to moderate severity. In clinical trials, 15% to 30% of patients experienced an asymptomatic transient rise in serum iron; hypotension and anaphylactoid reactions have occurred in less than 1% of the patients. The safety of MAGNEVIST® injection in patients with hemolytic disorders has not been studied.

REFERENCE: 1. Data on file, Berlex Laboratories, Inc.

BRIEF SUMMARY

INDICATIONS AND USAGE

MAGNEVIST® Injection is indicated for use with magnetic resonance imaging (MRI) in adults and children (2 years of age and older) to provide contrast enhancement in those intracranial lesions with abnormal vascularity or those thought to cause an abnormality in the blood-brain barrier. MAGNEVIST® Injection has been shown to facilitate visualization of intracranial lesions including but not limited to tumors.

MAGNEVIST® Injection is also indicated for use with MRI in adults and children (2 years of age and older) to provide contrast enhancement and facilitate visualization of lesions in the. spine and associated tissues. There is, however, only limited clinical experience in children for this indication.

CONTRAINDICATIONS

None known.

WARNINGS

The accepted safety considerations and procedures that are required for magnetic resonance imaging are applicable when MAGNEVIST® Injection is used for contrast enhancement. In addition, deoxygenated sickle erythrocytes have been shown in *in vitro* studies to align perpendicular to a magnetic field which may result in vaso-occlusive complications *in vivo*. The enhancement of magnetic moment by gadopentetate dimeglumine may possibly potentiate sickle erythrocyte alignment. MAGNEVIST® Injection in patients with sickle cell anemia and other hemoglobinopathies has not been studied.

Patients with other hemolytic anemias have not been adequately evaluated following administration of MAGNEVIST® Injection to exclude the possibility of increased hemolysis.

Hypotension may occur in some patients after injection of MAGNEVIST® Injection. In clinical trials two cases were reported and in addition, there was one case of a vasovagal reaction and two cases of pallor with dizziness, sweating and nausea in one and substernal pain and flushing in the other. These were reported within 25 to 85 minutes after injection except for the vasovagal reaction which was described as mild by the patient and occurred after 6-1/2 hours. In a study in normal volunteers one subject experienced syncope after arising from a sitting position two hours after administration of the drug. Although the relationship of gadopentetate dimeglumine to these events is uncertain, patients should be observed for several hours after drug administration.

Magnevist®
(gadopentetate
dimeglumine 469.01 mg/mL)
INJECTION

PRECAUTIONS - General

Diagnostic procedures that involve the use of contrast agents should be carried out under direction of a physician with the prerequisite training and a thorough knowledge of the procedure to be performed.

In a patient with a history of grand mal seizures, MAGNEVIST® Injection was reported to induce such a seizure.

Since gadopentetate dimeglumine is cleared from the body by glomerular filtration, caution should be exercised in patients with severely impaired renal function.

The possibility of a reaction, including serious, life-threatening, fatal, anaphylactoid or cardiovascular reactions or other idiosyncratic reactions should always be considered (see ADVERSE REACTIONS) especially in those patients with a known clinical hypersensitivity.

Animal studies suggest that gadopentetate dimeglumine may alter red cell membrane morphology resulting in a slight degree of extravascular (splenic) hemolysis. In clinical trials 15-30% of the patients experienced an asymptomatic transient rise in serum iron. Serum bilirubin levels were slightly elevated in approximately 3.4% of patients. Levels generally returned to baseline within 24 to 48 hours. Hematocrit and red blood cell count were unaffected and liver enzymes were not elevated in these patients. While the effects of gadopentetate dimeglumine on serum iron and bilirubin have not been associated with clinical manifestations, the effect of the drug in patients with hepatic disease is not known and caution is therefore advised.

When MAGNEVIST® Injection is to be injected using plastic disposable syringes, the contrast medium should be drawn into the syringe and used immediately.

If nondisposable equipment is used, scrupulous care should be taken to prevent residual contamination with traces of cleansing agents.

Repeat Procedures: If in the clinical judgment of the physician sequential or repeat examinations are required, a suitable interval of time between administrations should be observed to allow for normal clearance of the drug from the body.

Information for Patients:

Patients receiving MAGNEVIST® Injection should be instructed to:

1. Inform your physician if you are pregnant or breast feeding.
2. Inform your physician if you have anemia or any diseases that affect red blood cells.

LABORATORY TEST FINDINGS

Transitory changes in serum iron and bilirubin levels have been reported in patients with normal and abnormal liver function (See PRECAUTIONS - General).

CARCINOGENESIS, MUTAGENESIS, AND IMPAIRMENT OF FERTILITY

No animal studies have been performed to evaluate the carcinogenic potential of gadopentetate dimeglumine.

Gadopentetate dimeglumine did not evoke any evidence of mutagenic potential in the Ames test (histidine-dependent *Salmonella typhimurium*) nor in a reverse mutation assay using tryptophan-dependent *Escherichia coli*. Gadopentetate dimeglumine did not induce a positive response in the (C3H 10T1/2) mouse embryo fibroblast cellular transformation assay, nor did it induce unscheduled DNA repair synthesis in primary cultures of rat hepatocytes at concentrations up to 5000 µg/mL. However, the drug did show some evidence of mutagenic potential *in vivo* in the mouse dominant lethal assay at doses of 6 mmol/kg, but did not show any such potential in the mouse and dog micronucleus tests at intravenous doses of 9 mmol/kg and 2.5 mmol/kg, respectively.

The results of a reproductive study in rats showed that gadopentetate dimeglumine when administered in daily doses of 0.1-2.5 mmol/kg, did not cause a significant change in the pregnancy rate in comparison to a control group. However, suppression of body weight gain and food consumption and a decrease in the mean weights of testis and epididymis occurred in male rats at the 2.5 mmol/kg dose. In female rats a decrease in the number of corpora lutea at the 0.1 mmol/kg dose and the suppression of body weight gain and food consumption at the 2.5 mmol/kg dose were observed.

In a separate experiment, 16 daily intravenous injections were administered to male rats. At a dose of 5 mmol/kg of gadopentetate dimeglumine, spermatogenic cell atrophy was observed. This atrophy was not reversed within a 16-day observation period following the discontinuation of the drug. This effect was not observed at a dose of 2.5 mmol/kg.

PREGNANCY CATEGORY C.

Gadopentetate dimeglumine has been shown to retard development slightly in rats when given in doses 2.5 times the human dose, and in rabbits when given in doses of 7.5 and 12.5 times the human dose. The drug did not exhibit this effect in rabbits when given in doses 2.5 times the human dose. No congenital anomalies were noted in either species.

There are no adequate and well-controlled studies in pregnant women. MAGNEVIST® Injection should be used during pregnancy only if the potential benefit justifies the potential risk to the fetus.

NURSING MOTHERS

C^{14} labelled gadopentetate dimeglumine was administered intravenously to lactating rats at a dose of 0.5 mmol/kg. Less than 0.2% of the total dose was transferred to the neonate via the milk during the 24-hour evaluation period. It is not known to what extent MAGNEVIST® Injection is excreted in human milk. Because many drugs are excreted in human milk, caution should be exercised when the drug is administered to a nursing mother and consideration should be given to temporarily discontinuing nursing.

PEDIATRIC USE

Safety and efficacy in children under the age of 2 years have not been established. (See Indications and Usage and Dosage and Administration sections).

ADVERSE REACTIONS

The most commonly noted adverse experience is headache with an incidence of 8.7%. The majority of headaches are transient and of mild to moderate severity. In 42.3% of the cases it was felt that the headaches were not related to MAGNEVIST® Injection. Injection site coldness/localized coldness is the second most common adverse experience at 4.8%. Nausea occurs in 3.2% of the patients.

Localized pain, vomiting, paresthesia, dizziness and localized warmth occur in less than 2% of the patients.

The following additional adverse events occur in less than 1% of the patients:

Body as a Whole: Injection site symptoms, namely, pain, warmth, burning; localized burning sensation, substernal chest pain, fever, weakness, generalized coldness, localized edema, tiredness, chest tightness, regional lymphangitis, anaphylactoid reactions (characterized by cardiovascular, respiratory and cutaneous symptoms).

Cardiovascular: Hypotension, vasodilation, pallor, non-specific ECG changes, angina pectoris, phlebitis.

Digestive: Gastrointestinal distress, stomach pain, teeth pain, increased salivation.

Nervous System: Agitation, thirst, convulsions (including grand mal).

Respiratory System: Throat irritation, rhinorrhea, sneezing, dyspnea, wheezing, laryngismus, cough.

Skin: Rash, sweating, pruritus, urticaria (hives).

Special Senses: Tinnitus, conjunctivitis, visual field defect, taste abnormality, dry mouth, lacrimation disorder (tearing), eye irritation.

Laboratory: Transient elevation of serum transaminases.

The following other adverse events were reported. A causal relationship has neither been established nor refuted.

Body as a Whole: Back pain, pain, generalized warmth.

Cardiovascular: Hypertension, tachycardia, migraine, syncope, death related to myocardial infarction or other undetermined causes.

Digestive: Constipation, diarrhea.

Nervous System: Anxiety, anorexia, nystagmus, drowsiness, diplopia, stupor.

Skin: Facial edema, erythema multiforme, epidermal necrolysis.

Special Senses: Eye pain, ear pain.

Data from foreign studies did not reveal any additional adverse experiences.

OVERDOSAGE

The LD_{50} of intravenously administered gadopentetate dimeglumine injection in mice is 5-12.5 mmol/kg and in rats it is 10-15 mmol/kg. The LD_{50} of intravenously administered MAGNEVIST® Injection in dogs is greater than 6 mmol/kg.

Clinical consequences of overdose with MAGNEVIST® Injection have not been reported.

DOSAGE AND ADMINISTRATION

The recommended dosage of MAGNEVIST® Injection is 0.2 mL/kg (0.1 mmol/kg), administered intravenously, at a rate not to exceed 10 mL per minute. More rapid injection rates may be associated with nausea. The maximum total dose is 20 mL. Any unused portion must be discarded.

DOSAGE CHART

Body Weight (kg)	Dose in mL	Approx Duration of Injection in Seconds
10	2.0	20
20	4.0	30
30	6.0	40
40	8.0	50
50	10.0	60

To ensure complete injection of the contrast medium, the injection should be followed by a 5-mL normal saline flush. The imaging procedure should be completed within 1 hour of injection of MAGNEVIST® Injection.

Parenteral products should be inspected visually for particulate matter and discoloration prior to administration, whenever solution and container permit.

For full prescribing information, see package insert.

Caution: Federal Law Prohibits Dispensing Without Prescription.

Compensatory Mechanisms in Degenerative Neurologic Diseases

Insights From Parkinsonism

Donald B. Calne, DM, Michael J. Zigmond, PhD

• In animal models of parkinsonism, the ability to lose a substantial proportion of dopaminergic neurons without behavioral deficits does not derive from other systems taking over function of the dopaminergic pathway. The surviving nigrostriatal projection increases both the rate of synthesis and the release of dopamine, as compensatory adjustments. This capacity allows at least a fivefold rise in dopamine delivery per neuron, and this enhancement is potentiated further by receptor up-regulation. Decreased reuptake, due to loss of nerve endings, may also lead to augmented occupancy of dopamine receptors, and so constitute yet another compensatory mechanism. In humans, positron emission tomography has revealed subclinical impairment of the dopaminergic nigrostriatal pathway in subjects at risk for parkinsonism caused by 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine and Lytico-Bodig (the amyotrophic lateral sclerosis–parkinsonism dementia complex of Guam). However, the separation of patients with clinically overt idiopathic parkinsonism from controls is less marked in vivo (by positron emission tomography) than in postmortem analysis (by neurochemical assay). This disparity may be attributable to the reduction in the number of nigrostriatal nerve endings, leading, in vivo, to a relative increase of extracellular dopamine because active reuptake into the nerve endings is an important mechanism for removing dopamine from the synaptic cleft. In contrast, in a postmortem setting, dopamine that is not sequestered in the storage vesicles of nerve endings is readily available for biochemical degradation during the interval between death and brain analysis. Finally, it is also possible that differences may derive, in part, from dissimilar kinetic systems for handling exogenous and endogenous levodopa.

(*Arch Neurol.* 1991;48:361-363)

In seeking the cause of a degenerative disease, a first stage is the development of a conceptual model of pathogenesis. To formulate such a model, it is desirable to have information on the neurobiological adjustments that take place in the nervous system when some neurons have died and others are attempting to compensate and to maintain function. The most extensively studied pathway in this context is the dopaminergic component of the nigrostriatal bundle, and for this system, relevant animal observations can be correlated with phenomena observed in idiopathic parkinsonism.[1,2] In addition, since the dopaminergic cells of the zona compacta of the substantia nigra are selectively vulnerable to attrition with normal aging,[3] exploration of compensatory adjustments in these neurons should contribute to the elucidation of neurologic senescence. Thus, in this review we focus on animal and human studies of adaptations to lesions of nigrostriatal dopamine neurons.

ANIMAL STUDIES

6-Hydroxydopamine is a highly electroactive molecule that is concentrated by high-affinity transport systems of catecholaminergic neurons, particularly in the nerve terminals. Subsequent oxidation of this molecule produces highly toxic products, with resulting degeneration.[4] Injection of 6-hydroxydopamine into the brain of many experimental animals, either via the cerebrospinal fluid or directly along the nigrostriatal bundle, results in the death of dopaminergic neurons. The extent of the lesion depends on route of administration, dosage, and pharmacologic pretreatment.[1]

Gross behavioral changes do not occur following the administration of 6-hydroxydopamine unless the destruction of the nigrostriatal bundle is almost complete, and even then, the deficits are often transient.[1] Electrolytic lesions of the nigrostriatal system may also result in neurologic impairments that improve spontaneously,[5,6] and the same has been reported following administration of the toxin 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine to subhuman primates.[4]

The ability to undergo major loss of dopaminergic cells without clinical effects and the spontaneous improvement that commonly occurs when the lesions are severe enough to induce initial behavioral deficits do not reflect a transfer

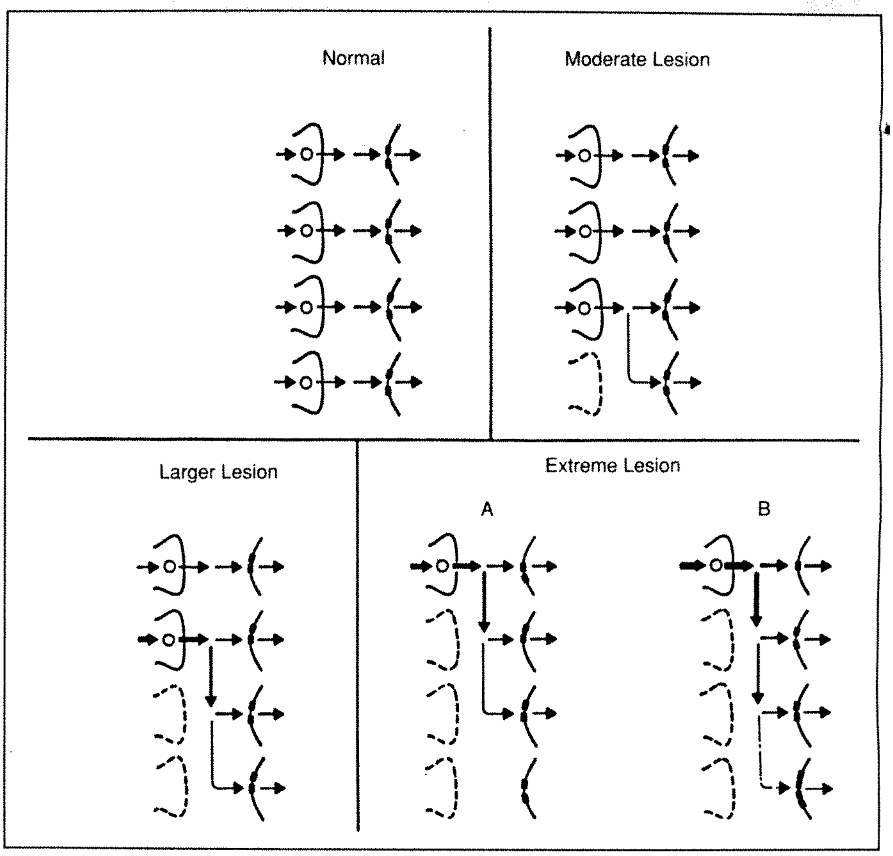
of function from the nigrostriatal bundle to other pathways. Neurologic deficits can readily be reestablished in lesioned animals by pharmacologic manipulations that compromise dopaminergic function still further. Indeed, lesioned animals are supersensitive to such treatments. Moreover, a minimal number of dopamine neurons must survive the lesion for recovery to occur.[6] These observations suggest the continued importance of the remaining elements of the nigrostriatal bundle.

The relation between size of an experimental lesion and neurologic deficit does not appear to derive from simple redundancy in the nigrostriatal system. The dopamine neurons that are spared by the injury have been shown to increase their synthesis and release of transmitter, suggesting an active, compensatory elevation in their functional activity.[7-9] The impact of this hyperactivity is augmented by the loss of sites for dopamine inactivation by reuptake due to degeneration of neighboring dopaminergic terminals[8,9] and, after extensive lesions, by an increase in the number of postsynaptic dopamine receptors[10] (Figure). Indeed, experiments have suggested that after partial nigrostriatal lesions, surviving dopaminergic neurons can increase their capacity to deliver transmitter by at least fivefold, and that the impact of this dopamine can be increased still further by receptor up-regulation. Taken together, these mechanisms may allow each surviving nigrostriatal neuron to compensate for the death of many similar cells before any functional deficit would be expected. Experimental observations at both the behavioral and the cellular levels are consistent with this prediction, and studies of damage to other monoaminergic systems in the brain and the periphery indicate that the capacity for such adaptation is widespread.[1]

It is possible that these compensatory processes exact a toll, however. The greatly enhanced turnover of dopamine could lead to the accumulation of toxic by-products of dopamine oxidation similar to those formed by 6-hydroxydopamine, thereby contributing to the ultimate degeneration of surviving elements of the nigrostriatal bundle. Furthermore, comparable toxic substances could accumulate in the extracellular space as a result of impaired removal of dopamine from the synaptic cleft consequent on loss of the nerve endings that possess an active reuptake mechanism. This vicious circle would generate more injury, to both dopaminergic and nondopaminergic cellular components.



A model for compensatory changes after lesions of the nigrostriatal bundle (from Zigmond and Stricker[1]). Top left, Under normal conditions synaptic transmission takes place with relatively little interaction between neighboring synapses. In addition, some synapses may be inactive. Top right, Moderate lesions have little or no functional impact for one or more reasons. Transmitter released at one synapse may act at a denervated site owing to the loss of inactivation via high-affinity uptake in that region (shown). There may also be some redundancy in the intact system, and previously silent synapses may become active (not shown). Bottom left, A larger lesion may require an increase in the synthesis and release of dopamine to keep postsynaptic function under dopaminergic control. A rise in the production of dopamine, together with the loss of high-affinity uptake sites, would result in a further increase in the field of influence of residual dopamine neurons (shown) and/or an increase in the postsynaptic response of innervated sites (not shown). Bottom right, After still larger lesions, rapid compensatory processes would be inadequate to restore function immediately. As a result, transmission would initially fail (A). However, a delayed compensation and recovery of function may occur (B). These additional compensations could include a gradual increase in the availability of tyrosine hydroxylase enzyme, a rise in the number of postsynaptic dopamine receptors, and the growth of new dopaminergic terminals.

OBSERVATIONS ON HUMAN SUBJECTS

As in the case of the animal models, postmortem analyses have indicated that neurologic deficits do not appear in idiopathic parkinsonism until the loss of striatal dopamine exceeds about 80%.[11] Moreover, concurrent measurements of the dopamine metabolite homovanillic acid suggest that degeneration of the nigrostriatal bundle is accompanied by an increase in dopamine turnover in humans as in laboratory animals.[12] Observations with positron emission tomography (PET) also indicate the presence of a substantial loss of nigrostriatal nerve endings in patients with clinically overt parkinsonism.[13-15] It is of interest from the viewpoint of documenting the compensatory potential of the human nigrostriatal pathway that PET has revealed subclinical damage to the nigrostriatal system in subjects with an increased risk of developing certain forms of parkinsonism.[16,17]

Postmortem analysis and PET also show normal age-related trends that are similar to, but less severe than, the changes found in idiopathic parkinsonism.[18,19] With this background, it has been proposed that the appearance and progression of clinical parkinsonism might result from age-related decompensation of an old subclinical nigrostriatal lesion.[20,21]

Positron emmision tomographic studies support the notion that animal experiments are clinically relevant. Moreover, the observations on animals also facilitate interpretation of PET. Since its inception, a persistent paradox has obscured the interpretation of PET with fluorodopa. Whereas human postmortem analyses of brains have revealed marked differences between striatal dopamine concentrations in normal and parkinsonian subjects, in vivo studies with PET have yielded less striking separation. This conflict may be resolved by taking into account the finding that in animals with partial lesions of the nigrostriatal bundle, the removal of dopamine from the synaptic cleft is substantially impaired because the decreased number of dopaminergic nerve endings means that active reuptake is decreased. Thus, whereas the intracellular content of striatal fluorodopamine formed from the exogenous fluorodopa PET tracer would be reduced by lesions of the nigrostriatal bundle, the accumulation of extracellular fluorodopamine might be enhanced. These predictions have recently been confirmed by direct neurochemical measurements in 6-hydroxydopamine–lesioned animals treated with L-dopa.[22] Since PET cannot distinguish between intracellular and extracellular pools of labeled compounds, the technique can be expected to provide an index of the parkinsonian striatal deficit that is consistently closer to normal values than estimates obtained from postmortem studies. Furthermore, in the postmortem setting, dopamine that is not sequestered in the storage vesicles of nerve endings is more readily available for biochemical degradation during the interval between death and brain analysis. This is conducive to increasing the separation of neurochemical findings between patients with idiopathic parkinsonism and normal subjects. Finally, it is also possible that the difference may derive, in part, from dissimilar kinetic systems for handling exogenous and endogenous levodopa.

COMMENT

The considerable power of adaptive mechanisms in certain neural pathways has implications for the search for the pathogenesis of neurodegenerative disease. In the case of degeneration of the nigrostriatal dopamine neurons, substantial compensatory events may occur and could interfere with the detection of functional impairments for an extended period of time.

If a similar situation obtains in the other common neurodegenerative disorders, there may be a shared category of pathogenesis in which early causal events occur without recognition because compensatory mechanisms preclude clinical expression. Moreover, the compensatory activity may have long-term deleterious effects. Further analysis of the neurobiology of compensatory adjustments might allow the development of improved methods for the detection and treatment of a variety of neurologic disorders.

Corpus Callosotomy for Intractable Seizures in the Pediatric Age Group

Richard E. Nordgren, MD; Alexander G. Reeves, MD; Adele C. Viguera; David W. Roberts, MD

• The results of corpus callosotomy in 18 patients 16 years old and younger are presented. Eighty-three percent of our patients have had a significant improvement from the surgery (a decrease in seizure frequency of greater than 80% or no longer having generalized atonic, tonic, or tonic-clonic seizures). The procedure seems to be well tolerated in young patients, and we have not noted a postoperative deterioration in behavior, memory, or language function in our patients. One of our patients died in status epilepticus 3 months after surgery. Nevertheless, we have not encountered any serious morbidity in our other patients. Corpus callosotomy can be considered for children with intractable seizures, especially when generalized atonic, tonic, or tonic-clonic (whether primary or secondary) seizures are the major seizure type.

(*Arch Neurol.* 1991;48:364-372)

Corpus callosotomy is becoming a more widely used procedure in the treatment of intractable epilepsy and has been carried out in many patients in the pediatric age group. However, there have been very few series that have reported results in children exclusively.[1-4] The purpose of this article is to present the results of callosotomy performed in 18 children 16 years old and younger at the Dartmouth-Hitchcock Medical Center, Hanover, NH, and to review the results of callosal sectioning in children from other series reported in the literature.

PATIENTS AND METHODS

Our patients have had diverse causes of their epilepsy, including neonatal complications, infantile spasms, porencephaly, viral encephalitis, acute infantile hemiplegia, Rasmussen's syndrome, and Sturge-Weber syndrome. Also, several patients have been diagnosed as having Lennox-Gastaut syndrome secondary to various causative factors. The indications for corpus callosotomy in our series were as follows: (1) medical intractability of seizures (at least 4 years of intractable seizures with the attempted use of all standard anticonvulsants); (2) seizure type potentially amenable to callosotomy (particularly generalized atonic, tonic, or tonic-clonic seizures); (3) potential functional benefit if improvement in seizure control is achieved; (4) no single epileptiform focus identified.

Potential cases were evaluated by history, physical examination, neuroimaging, electroencephalography (EEG), neuropsychological testing, and Wada test when feasible. Long-term video-EEG monitoring and magnetic resonance imaging scanning have been carried out on patients since 1987.

Patients in this series who were operated on between 1971 and 1980 have been included in previous reports.[5-7] Six of our patients have had a complete callosal section performed in one operation, three patients have had only an anterior callosotomy, while nine patients have had a two-stage complete callosotomy. Complete callosal section, early in the series, included division of the entire corpus callosum (together with the underlying hippocampal commissure, one fornix, and the anterior commissure[5]); anterior callosotomy included division of approximately the anterior two thirds of the callosum; and two-stage commissurotomy included division of the entire corpus callosum and hippocampal commissure.[8] While most patients with anterior section will also need the posterior third sectioned, we now stage the corpus callosum section to prevent the side effects of total section in those who may not need the entire operation. One patient who had evidence for predominantly posterior seizure activity had the posterior callosum sectioned first.

We have used the International Classification of Epileptic Seizures (ICES)[9] for our patients' seizures. Most of our patients have had their seizures classified by historical data, for we have had video-EEG monitoring available at our institution only since 1987 (Table 1). We have also used the ICES for 50 patients reviewed from the literature who were 16 years old or younger at the time of their surgery (Table 2).[1-4,10-16] We feel that there are adequate data to classify the 50 patients' seizures, although the clinical details of the seizures vary and often there is a very limited description of the seizures. In our classification, we have included generalized tonic and generalized tonic-clonic seizures together and focal myoclonic seizures with simple partial seizures.

RESULTS

Effect on Seizures

Of the 86 patients who have undergone corpus callosotomy at the Dartmouth-Hitchcock Medical Center, 18 have been 16 years old or younger at the time of surgery and have had greater than 2 years of follow-up. Table 1 summarizes the clinical data on these patients, while Table 2 summarizes clinical data on 50 patients from the literature who have undergone corpus callosotomy by age 16 years. Table 3 summarizes the results of our patients and the patients from the literature using frequency of all seizures for the two groups, and Table 4 summarizes the results of callosotomy by seizure type for the two groups.

As can be seen from Table 3, the majority of our patients have had a greater than 80% reduction in overall seizure frequency. Also, one patient in the "50% to 80% reduction" group and one patient in the "no significant change" group are no longer having incapacitating seizures and can be considered much improved in

regard to their quality of life.

Table 4 summarizes our results by seizure type, and, as can be seen, more incapacitating seizures were quite likely to improve after corpus callosotomy. Eighty percent of our patients and 71% of the patients reviewed with primary generalized tonic or tonic-clonic seizures had either a greater than 80% reduction or no seizures of this type postoperatively. All of our patients and 60% of the patients reviewed with secondary generalized seizures had at least an 80% reduction in the number of this type of seizure postoperatively. With seizures associated with a sudden fall to the ground (generalized atonic or generalized myoclonic with falling), 11 (92%) of 12 of our patients are no longer having this type of seizure, and one patient has had an 80% seizure reduction. In the reviewed patients, 11 (65%) of 17 are no onger having this type of seizure, while two (12%) have had a greater than 80% reduction. The frequency of generalized absence seizures and complex partial seizures without generalization have also improved postoperatively in most of our patients.

Simple partial seizures are the most common seizure type present after surgery. Fifteen of our patients have had simple partial or focal myoclonic seizures after surgery, and in nine of these patients, the focal seizures are a new phenomenon. One patient developed a new type of simple partial seizure after surgery with more intense manifestations than in his previous focal seizures (about once per month he has a partial seizure with slumping to the ground), and one patient developed more frequent simple partial seizures after surgery, but was no longer having generalized atonic or tonic-clonic seizures. While we have had one patient develop complex partial seizures as a new seizure type postoperatively, there have been no patients with generalized atonic, absence, or tonic-clonic seizures postoperatively who did not have this type of seizure prior to surgery.

EEG Changes

The EEG changes in our patients following surgery were similar to those reported in other series.[17,18] Fifteen of our patients had clearly synchronous bursts of epileptiform activity prior to surgery and after callosotomy; nine of these had no synchronous bursts noted on postoperative EEGs, four had a markedly decreased frequency of synchronous bursts, and two had no obvious decrease in the frequency of synchronous bursts. Seven of our patients had clearly demonstrated independent epileptiform discharges from either hemisphere prior to surgery. Postoperative EEGs in these patients demonstrated only unilateral discharges in four patients, two patients had no significant change in the independent discharges, and one patient had no independent unilateral discharges on postoperative EEGs. Usually there was no change noted in background activity after surgery. It is difficult to extrapolate too much from the above data, since the EEGs in most of our patients are not prolonged recordings and mostly interictal samplings. However, it is suggestive that in many of our patients the synchronous discharges in fact represent secondary bilateral synchrony and that the corpus callosum is important for the development of these bilateral discharges.

Behavioral Changes

Transient "mutism" and paresis of the nondominant leg have been a minimal and short-lived problem in patients who have had a two-stage procedure,[19] while more severe difficulties were seen in some of the earlier patients who underwent a complete section. Our patients have all adapted to the chronic right/left afferent disconnection that follows section of the posterior half of the callosum.

Neuropsychologic testing was attempted in all of our patients prior to surgery, and there were no patients who had a significant deterioration in the test scores postoperatively. We have not noted the development of new language problems as reported by oth-

ers following surgery.[20] Also, none of our patients have had an increase in, or development of, violent behavior or other behavioral problems. Many patients have had a very marked improvement in their behavior and alertness after callosal sectioning, presumably on the basis of decreased seizures and lower levels of anticonvulsant medications.

COMMENT

Corpus callosotomy has been used for the treatment of intractable seizures since 1939, when Van Wagenen and Herren[10] first introduced the procedure. However, it was not until the 1970s that this procedure became widely used, and there have been very few reports limited to children. Our results in 18 patients have been quite similar to those reported in large series of patients of all ages. For comparison, we have reviewed the published series of patients and analyzed the results in 50 patients 16 years old or younger for whom there are sufficient data to determine the types of seizures occurring preoperatively and for whom there are also postoperative seizure data (Table 2). Except for a series by Van Wagenen and Herren, there have been follow-ups of at least 6 months in the reviewed cases.

Corpus callosotomy should not be expected to eliminate seizures (even though we have had one child and there were six children reported who are seizure free after callosotomy) but, rather, to ameliorate more disabling seizures. Analysis by seizure type gives a better indication as to the expected results of callosal sectioning, and our results and those of the patients reviewed demonstrate that callosotomy can dramatically reduce the frequency of more disabling seizures (generalized atonic, tonic, and tonic-clonic).

When considering corpus callosotomy as a means of seizure control for a patient with intractable epilepsy, one must determine whether the patient is having seizures of a type that are likely to respond to the surgery. Also, one must consider whether the clinical description of the seizure allows one to classify accurately patient's seizures. We have found that, even with video-EEG monitoring, it is not always possible to exactly classify patient's seizures. If, however, seizures are considered on the basis of the most obvious clinical feature during the actual seizure, one can use historical data or clinical observation of seizures for a classification that is clinically very useful when assessing whether the patient may or may not be a candidate for callosotomy. With this in mind, we have considered two groups of seizures on the basis of obvious outcome of the seizure, regardless of the classification using the ICES criteria. The first are brief seizures during which the patient has a sudden fall to the ground, either because of a loss of tone or because of a positive phenomena (ie, a myoclonic jerk). The second is the combined group of generalized tonic or tonic-clonic seizures, with focal or generalized onset. The exact mode of onset or exact clinical manifestations do not appear to be crucial when trying to categorize patient's seizures into these two groups, and we have found that the response to callosotomy is not appreciably different if one considers subgroups of the larger two groups.

Brief seizures with falls are devastating to patients, often resulting in injuries and restricting patients' ability to function independently. These seizures usually occur many times per day and are often the most refractory to control with anticonvulsants. Table 5 combines

*Patient no longer having myoclonic seizure with falling postoperatively.

†Two patients had simple partial seizures without generalization postoperatively.

the results for brief seizures with a sudden fall to the ground (generalized atonic and myoclonic with falling) for our patients and the reported patients. These data would indicate that corpus callosotomy is an effective treatment for these types of seizures in that all of our patients have had at least an 80% reduction of these debilitating seizures (92% no longer having these types of seizures), while 76% of the patients reviewed have had at least an 80% reduction (65% no longer having these types of seizures).

Obviously, generalized tonic and generalized tonic-clonic seizures are also disabling to a patient. As noted above, it is often very difficult to tell on the basis of description whether these are primary generalized or secondary generalized seizures and, therefore, we have combined the results for all generalized major motor convulsions in Table 6. In our series, 15 (88%) of 17 patients have had at least an 80% or greater reduction of generalized tonic or tonic-clonic seizures, and, in the patients from the literature, 31 (69%) of 43 patients have had at least an 80% reduction in these seizures.

Both in our series of patients and in those reviewed, simple partial seizures were frequent following surgery (15 of our 18 patients) and, in nine of these patients, the focal seizures were a new type. One of our patients and one of the patients reviewed developed more intense focal seizures. Many generalized seizures were converted to focal seizures, but almost always the focal seizures were considered less disabling to the patient.

The above data indicate that corpus callosotomy is an effective procedure for the treatment of intractable generalized seizures in young patients. The data also show that many patients with complex partial seizures will improve. There has been a less predictable response for simple partial seizures, and many patients have had their generalized seizures converted to more focal seizures. In our series, we have had one patient who developed complex partial seizures as a new seizure type postoperatively and we have had no patients with persisting tonic or tonic-clonic generalized convulsions and akinetic or absence seizures who did not have this type of seizure preoperatively.

Our present approach is to carry out the callosal section as a two-stage procedure to spare patients the potential effects of total disconnection. If there has not been a significant improvement in seizure control after the first stage, completion of the section is performed. There have been series where only partial corpus callosotomy has been performed,[4,16] but it has been pointed out previously that there is more likely to be improvement in seizures after a complete section than after a partial section.[21] This has been our experience. Of our 12 patients who initially had a partial section (posterior section was performed first in one patient), three had significant improvement after the first stage and had no further surgery and nine patients had completion of their section because of no major improvement after the first stage. Of these nine patients, seven had significant improvement after the second stage was performed. In the reviewed patients, 19 have had only a partial section with an "excellent" response in nine patients (47%), while 23 (74%) of the 31 patients who had a total section (in one or two stages) had an "excellent" response. These data would strongly support the consideration for a second-stage procedure if the first stage has not been helpful in controlling seizures. We have not yet been able to predict which patients will only need a single procedure, using either clinical or EEG data.

Sectioning of the corpus callosum can result in several types of behavioral and psychologic problems postoperatively. Since we have been carrying out callosotomy as a two-stage procedure, we have not had the "acute disconnection syndrome" as a major problem postoperatively. Some of our patients have had a very mild and transient hemiparesis that usually has resolved in a few days, and we have not had any patients develop persistent mutism postoperatively. We have attempted neuropsychologic testing in all of our patients, but this has not been feasible in many of them who are too retarded to test. Since we have initiated Wada testing on our potential callosotomy patients, none of our young patients have demonstrated the ability to be reliably tested for language and memory function and, therefore, have not had this procedure performed. Nevertheless, none of our patients has developed new memory or speech problems postoperatively. We have not noted the psychologic deterioration found by Sass et al[20] in some of their patients. Less extensive neuropsychologic test batteries have been routinely conducted in our patients when compared with the series of Sass et al, so subtle changes may have been missed. In the 50 patients reviewed, there has been definite deterioration noted in speech, memory, language function, or behavior in only one patient (patient 11 in the series by Spencer et al[15] and Sass et al). This patient appears to have had a significant deterioration in speech, verbal memory, and right arm function postoperatively. He had a right hemiparesis and left cerebral hemiatrophy demonstrated by neuroimaging, but had right hand preference and right-hemisphere language dominance; memory function was demonstrated in the right hemisphere only.

There may be several reasons why these problems are not seen more frequently in young patients. While these may be present but not observed, it is more probable that the younger patients have had a high incidence of a severely compromised hemisphere at the time of surgery and, as a consequence, language and memory function has been unilateral. Also, the younger nervous system may be better able to accommodate to the changes resulting from callosotomy. Lassonde et al[3] were able to demonstrate in a small series that younger patients were less affected by complete callosal sectioning when

Table 5.—Results Combining Generalized Atonic and Myoclonic Seizures With Falling to the Ground

No significant change	2	10
Increased seizures postoperatively	0	1

tested for unilateral discrimination and interhemispheric transfer of tactile information. The authors speculated that younger children could use extra callosal connections for interhemispheric transfer of information. Nevertheless, hemispheric memory and language function should be elucidated in patients preoperatively, if at all possible, and the possible deleterious effects on motor, language, and speech functioning of callosotomy must be kept in mind, especially when there is no evidence for same hemisphere dominance for hand and speech function.[20]

In our series and others, patients who have had evidence for unilateral disease, either on clinical examination or with neuroimaging, have tended to have the best results from surgery,[1,14] while less predictable results have been obtained in patients with evidence of diffuse pathogenicity or causes such as infantile spasms, Lennox-Gastaut syndrome, and asphyxia. This is especially true when these patients are suffering from hundreds of seizures per month or having frequent episodes of status epilepticus (including our one patient who died in status epilepticus 3 months after the procedure). Of our eight patients with clear unilateral pathogenicity, one has been seizure free, six have had a greater than 80% reduction in their seizure frequency, and one patient has had a 50% to 80% reduction in seizure frequency. Six of the 10 patients with no clear unilateral pathogenicity have had a greater than 80% reduction in seizure frequency, three have had no significant change, and one patient has died in status epilepticus. Further study is necessary to define criteria that will select patients with severe diffuse pathologic findings who most likely will respond to the surgery.

Some authors have considered mental retardation a relative contraindication for callosotomy,[6,15] but our experience has not borne this out.

Callosotomy should be considered in young patients when generalized atonic, tonic, and tonic-clonic seizures are occurring frequently. The deleterious effects of frequent recurrent seizures and the possibility of "kindling" leading to more refractory seizure foci over the years[22] may add to the surgical rationale for early surgical intervention. Young patients appear to tolerate the procedure better than do older patients, and an improvement in control of the seizures will often improve their behavior and cognitive functioning.

Intraputaminal Infusion of Nerve Growth Factor to Support Adrenal Medullary Autografts in Parkinson's Disease

One-Year Follow-up of First Clinical Trial

Lars Olson, MD; Erik-Olof Backlund, MD; Ted Ebendal, PhD; Robert Freedman, MD; Bertil Hamberger, MD; Per Hansson, MD; Barry Hoffer, MD; Ulf Lindblom, MD; Björn Meyerson, MD; Ingrid Strömberg, PhD; Olle Sydow, MD; Åke Seiger, MD

• Experimental studies in rodents show that β–nerve growth factor can increase the survival, neurite outgrowth, and functional effect of grafts of adrenal chromaffin cells to the basal ganglia. We, therefore, have begun to investigate whether treatment with nerve growth factor might also increase the functional effect of autografts of adrenal medullary tissue in patients with Parkinson's disease. Previous studies have shown that stereotactic implantation of adrenal tissue pieces produces a transient functional improvement that lasts for a few months. This report describes a trial of grafting of adrenal chromaffin tissue into the putamen, supported by infusion of nerve growth factor. The patient is a 63-year-old woman with a 19-year history of Parkinson's disease, now complicated by on-off phenomena and drug-induced hyperkinesia, despite optimized medical management. The left adrenal gland was removed, and the medulla was dissected into 1- to 2-mm^3 pieces in a solution containing nerve growth factor purified from mouse submandibular gland. Pieces were implanted in six tracts 3 to 4 mm from a previously placed cannula in the left putamen. Through the cannula, nerve growth factor was infused for 23 days for a total dose of 3.3 mg. Clinical assessment consisted of global ratings for rigidity and/or hypokinesia and for drug-induced hyperkinesia. Measures of gait and fine-motor control were also made. The motor readiness potential and auditory evoked potentials were recorded. The patient underwent follow-up closely for 4 months before and 13 months after grafting. She experienced no ill effects from any of the procedures, and antibodies to murine nerve growth factor, which closely resembles human nerve growth factor in amino acid sequence, did not develop. In the first postoperative month, she had a marked decrease in rigidity on the right side and a decrease in hyperkinesia. As with other patients with adrenal grafts but without nerve growth factor support, this improvement diminished during the second month. However, unlike these previous patients, our patient continued a slower phase of improvement that appears to have extended for at least the next 11 months. This course of improvement can be seen in the scores from global ratings of hypokinesia and/or rigidity, as well as amplitude of the motor-readiness potential. In addition, there was a tendency toward a decrease in the number of steps she needed to reverse direction while walking. There was no change in scores for hyperkinesia, speed of walking, or tests of fine motor control. From this single-patient study, it is not possible to draw conclusions about the mechanism of therapeutic effect or the eventual clinical utility of this approach. It seems, however, that nerve growth factor treatment may be safe in human beings and that it may prolong the effect of adrenal chromaffin grafts, consistent with earlier basic science findings.

(*Arch Neurol.* 1991;48:373-381)

Extensive evidence accumulated from basic laboratory investigation on neuronal transplantation suggests that various sources of catecholamine-containing cells might provide a functional substitute for degenerating substantia nigra neurons in patients with Parkinson's disease.[1-6] Experimental data in rodents suggested that both fetal substantia nigra neurons[7,8] and adult chromaffin cells from adrenal medulla[9] might have such potential. However, fetal substantia nigra neurons appear to produce their functional effects in denervated rat caudate by forming a new dopaminergic innervation, whereas adrenal chromaffin cells synthesize and release dopamine and noradrenaline to diffuse into the caudate, and do not form nerve fibers or synapses.[1,2] Because of the difficulties involved with fetal grafting, including the potential need for lifelong immunosuppression, adrenal tissue was chosen for the initial clinical trials.[10,11] This tissue source has the distinct advantage of being available as an autograft, ie, from the patient's own adrenal medulla. Stereotactic implantation of adrenal medullary cells into the putamen of patients with Parkinson's disease produces a decrease in several parkinsonian symptoms. These effects include immediate marked improvements lasting for a day or two, probably caused by acute release of large amounts of catecholamines from the grafts, as well as more subtle improvements, particularly in the "off" symptom phase, that last, at most, a few months. However, all changes generally disappear by 90 days.[12] To provide a longer-lasting effect, other approaches have been tried. Open neurosurgical implantation of large pieces of adrenal medulla into the caudate nucleus showed initial promise,[13] but further clinical trials were less encouraging, and the morbidity and mortality were greater than that experienced with stereotactic implantation.[14,15] Human fetal dopamine neuroblasts produce longer-lasting change,[16-18] which suggests that the fiber outgrowth from the graft may be critical for more prolonged therapeutic effect. However, the problems of immunosuppression, infection, and other disadvantages of the fetal tissue source remain.

Several ways in which the efficacy of chromaffin grafts might be increased are known (for further review, see reference 19). Perhaps the most straightforward and best supported by animal data[20-22] would be to infuse nerve growth factor into the grafted area for a period of time after grafting. When chromaffin tissue is implanted into the dopamine-denervated rat striatum, temporary

nerve growth factor infusion has several, apparently permanent, beneficial effects. First, many more chromaffin cells survive. Second, many of these cells transform into neuronal phenotypes, so that the host striatum becomes innervated by a network of graft-derived catecholamine-containing nerve fibers. Third, long-term functional recovery is improved, as measured by a reduction in apomorphine-induced rotations 1 year after grafting.

In the present report, we describe a technique of growth factor administration to the brain and the results of the first attempt to support chromaffin autografts in a patient with severe Parkinson's disease by intraputaminal infusion of nerve growth factor during the first postoperative month. No negative effects could be ascribed to the nerve growth factor treatment. Parkinsonian symptoms gradually declined in this patient and, 1 year after cessation of nerve growth factor treatment, the scores on some clinical rating scales are still significantly better than those recorded preoperatively. We, therefore, conclude that the technique of using nerve growth factor support for stereotactically implanted chromaffin autografts represents a viable experimental approach for further investigation of grafting strategies in Parkinson's disease.

PATIENT AND METHODS

Selection Criteria

Our general inclusion criteria were as follows: The patient should be younger than 65 years of age and have severe hypokinesia as a major symptom. There should be no other confounding diseases or disabilities. The patient must also be psychologically stable and not demented. Finally, there must be a clear response to levodopa therapy, but inadequate relief of symptoms, such as the presence of on-off phenomena, in spite of an optimized drug regimen. Informed consent was obtained from the patient, and all procedures had been approved by the Ethical Committee of the Karolinska Institute, Stockholm, Sweden.

Patient History

This woman was 63 years old at the time of grafting and had a history of Parkinson's disease for 19 years. The patient did well on levodopa treatment for about 10 years, when on-off symptoms appeared. Despite more frequent and higher doses of levodopa, and the addition of bromocriptine, symptoms became progressively more disabling. During daytime, the symptoms changed rather randomly between severe hypokinesia and hyperkinesia, with the latter dominating. There were only brief periods (lasting some minutes) of relatively normal motor control in between. The patient was rated as being in stage 4 according to the scale of Hoehn and Yahr.[23] Apart from the symptoms of parkinsonism, the patient was neurologically normal as judged from a computed tomographic scan of the brain and was otherwise healthy.

During preoperative morning off symptom periods when the morning medications were omitted for recording of readiness and auditory evoked potentials, the patient was rigid and bedridden or confined to a wheelchair. She could not move from the wheelchair to the examination table and back without considerable assistance.

Study Design

The patient was brought to the hospital regularly for clinical tests for 4 months prior to the operation and was admitted to the hospital for a continuous stay 3 weeks before and 3 weeks after the operation. Her optimized drug regimen (levodopa, 600 ± 100 mg; bromocriptine, 35 mg; and amitriptyline, 75 mg; divided into 11 daily doses) was maintained essentially unchanged until 7 months postoperatively, when selegiline became available and was added. Clinical assessments of symptoms were carried out regularly by experienced examiners as described below. The test battery was based partly on our previous studies[10,12,17] and included clinical scoring of symptoms, walking tests, pegboard tests of fine motor control, and neurophysiological recordings of readiness and auditory-evoked potentials.

Nerve Growth Factor Preparation and Purification

β-Nerve growth factor was purified from 400 male mouse (NMRI, body weight >30 g) submandibular glands, as previously described.[24,25] Elution from the second column of CM-Sepharose was by a linear gradient of sodium chloride,[25,26] yielding a peak of highly purified β-nerve growth factor (Fig 1). The concentration of nerve growth factor was determined from the specific absorbance at 280 nm (1.6 at 1 mg/mL in a 1-cm cuvette). Identity and purification was further verified by electrophoresis in sodium dodecylsulfate on a gradient polyacrylamide gel, and by immunoblotting of similar gels (Fig 1).

Purified, biologically active nerve growth factor was dialyzed against Ringer's solution with glucose, sterile-filtered twice, and tested for sterility using official standard high-stringency conditions as required for injectable substances by the European Pharmacopeia. It was then packed in syringes provided by the pump manufacturer (see below). Filled syringes were kept at 8°C until use. The final concentration of nerve growth factor in the syringes used for infusion was 600 μg of β-nerve growth factor per milliliter in the Ringer's solution with glucose, corresponding to 60 000 biological units per milliliter. The rationale for the use of mouse nerve growth factor is presented in the discussion.

Bioassay of Nerve Growth Factor Activity

The biological activity of nerve growth factor was measured in a nerve fiber outgrowth assay with explanted sympathetic ganglia from the 9-day-old chick embryo. The dissected ganglia were explanted into a collagen matrix.[25,27] Details of the technique have recently been presented.[28] To determine activity, the purified mouse nerve growth factor was added in a series of twofold dilutions, with final concentrations ranging from 0 to 20 ng/L. The cultures were incubated at 37°C using 5% carbon dioxide and 92% relative humidity. After 1 to 2 days, the cultures were examined in an inverted microscope equipped for phase-contrast and dark-field illumination. Activity tests of the nerve growth factor preparation showed that 5 ng of nerve growth factor per milliliter evoked a dense circular fiber halo, regarded as corresponding to an activity of 1 biological unit. This was the case also after dialysis and sterilization (Fig 1). In addition, samples of nerve growth factor remaining in the tubing and in the dead volume of the syringes were analyzed after being recovered from the patient. There was no loss of biological activity in these samples, as shown by the serial dilutions.

Enzyme Immunoassay for Antibodies to Nerve Growth Factor

Blood was drawn preoperatively and 2, 4, and 10 weeks postoperatively to detect possible immunization against the infused mouse nerve growth factor. An immunoassay (enzyme immunoassay) for nerve growth factor antibodies (Fig 1) was designed based on principles described in detail elsewhere.[29] Immunoplates (96-well multidishes, Nunc, Copenhagen, Denmark) were coated with the purified mouse β-nerve growth factor (1 μg/mL) in 0.05 mol/L of carbonate buffer (pH, 9.6). Each well received 50 μL, and the dishes were incubated at 4°C overnight. The immunoplates were blocked for 1 hour at room temperature with 1% bovine serum albumin in the same buffer. After washing with TRIS-buffered saline (0.02 mol/L of TRIS hydrochloride, pH, 7.4; 0.5 mol/L of sodium chloride, containing 0.5% Tween 20), dilutions (10^{-2} to 10^{-11}) of serum from the patient (in TRIS-buffered saline with 0.05% Tween 20) were added for an overnight incubation at 4°C. The plates were then washed extensively at room temperature, before incubation with biotinylated antibodies to human IgG (0.5 μg/mL; Vector Laboratories, Burlingame, Calif) for 30 minutes. Finally, β-galactosidase conjugated to streptavidin (Bethesda Research Laboratories, Gaithersburg, Md) was added for 15 minutes at a dilution of 1:5000, and the plates were subsequently washed. To start the enzyme reaction, 100 μL of reaction[29] buffer was added to each microwell with 100 μL of 0.2 mmol/L of methylumbelliferyl-β-galactoside. The resulting methylumbelliferone (excitation wavelength, 365 nm; emission wavelength, 450 nm) was assayed in a microplate fluorometer (Microfluor, Dynatech, Burlington, Mass). The results were plotted as a function of the serum concentration.

Surgical and Neurosurgical Procedures

Preoperative workup included a computed tomographic scan of the abdomen that demonstrated two normal-sized adrenal glands. Plasma catecholamine concentrations were determined,[30] and the results showed normal basal levels of noradrenaline and adrenaline.

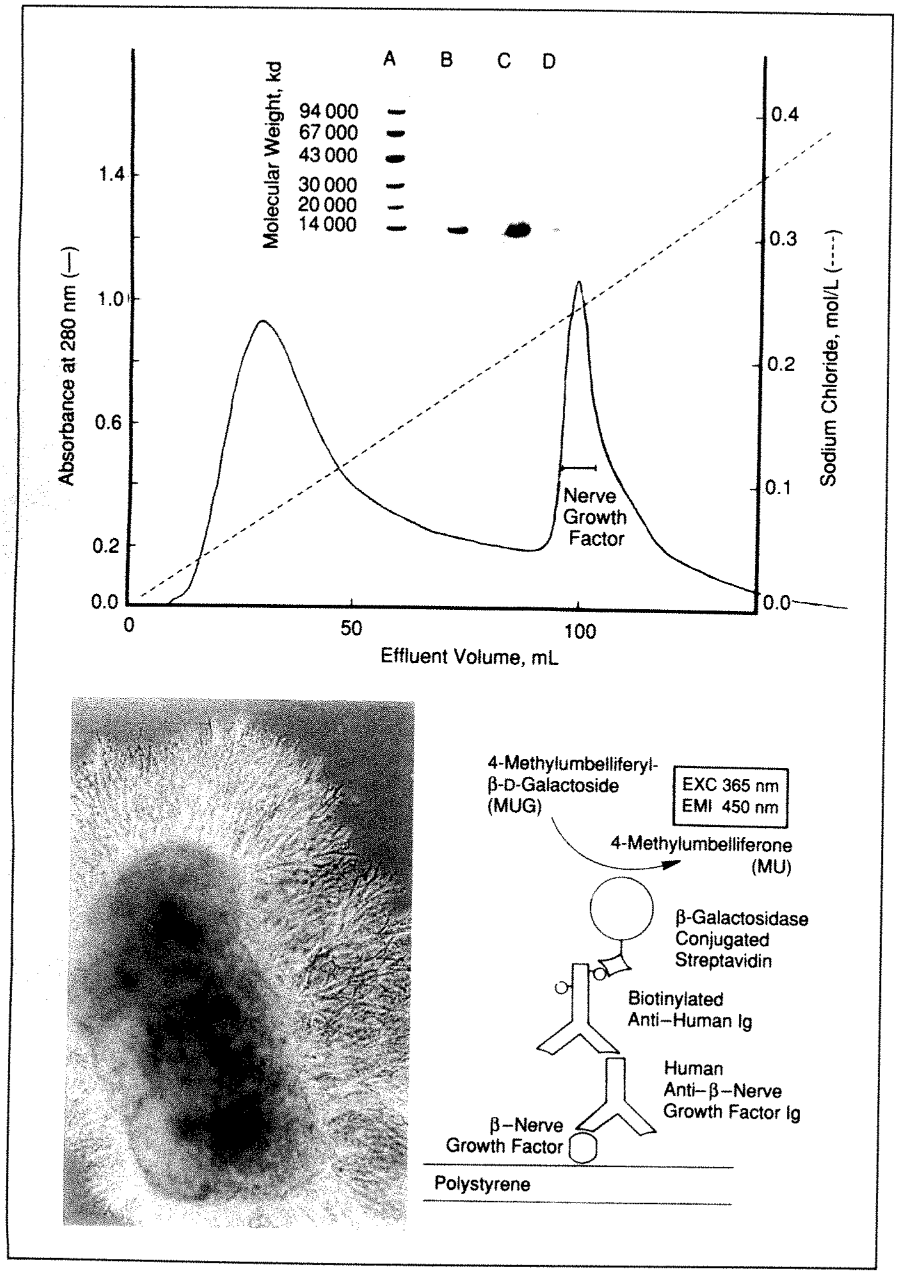

Fig 1.—Top, Elution profile of β–nerve growth factor from the second column of CM-Sepharose used in the purification.[24-26] The actual nerve growth factor peak (marked by the horizontal bar shown in this figure) was used for infusion to the patient described in this report. Inserts: A shows standard proteins of known molecular weight (14 000 to 94 000 kd) stained by coomassie blue after electrophoresis in sodium dodecylsulfate on a gradient polyacrylamide gel. B shows a similar experiment with nerve growth factor from the peak eluted by sodium chloride from the CM-Sepharose. Five micrograms of nerve growth factor protein was loaded in the lane. A main band (molecular weight, 14 000 kd) is apparent in this preparation in accordance with the molecular weight of 13 300 kd known from sequence data. C and D show immunoblots of β–nerve growth factor from gels similar to that shown in lane B. After transfer to nitrocellulose paper, the protein was incubated with antibodies raised to mouse β–nerve growth factor for subsequent detection of antibody binding by secondary biotinylated antibodies followed by incubation with iodine 125–streptavidin and x-ray autoradiography. The labeled bands again show a single major component with an apparent molecular weight of 14 000 kd. The lanes were loaded with 2 μg and 20 ng of nerve growth factor protein, respectively. Lower left, The biological activity of nerve growth factor given to the patient. After dialysis against Ringer's solution with glucose and subsequent sterilization by membrane filtration, a fraction of the nerve growth factor solution intended for infusion was diluted from 800 μg/mL to 12 ng/mL and incubated with a sympathetic ganglion from a chick embryo.[25,27,28] The activity of the nerve growth factor results in a massive nerve-fiber outgrowth after 1 day of culture as seen in this phase-contrast micrograph. Bottom right, The principle of the enzyme immunoassay used to test for the possible appearance of antibodies to the mouse β–nerve growth factor in the serum of the patient. A 96-well immunoplate was coated with the purified mouse β–nerve growth factor (1 μg/mL) and then blocked with serum bovine albumin. Different dilutions of serum samples taken before and at regular time points during and after the patient's treatment were then incubated in the wells. Possible antibodies binding to the coat of nerve growth factor were detected by incubation with biotinylated antibodies to human immunoglobulin followed by a conjugate of β–galactosidase and streptavidin. Resulting enzyme activities were measured by fluorometry of the product 4-methylumbelliferone. EXC indicates excitation wavelength; EMI, emission wavelength.

The neurosurgical procedures were essentially as previously used by us.[10,12] This time, however, six cylinders of adrenal medullary tissue were introduced, arranged around a central polyurethane catheter with an outer diameter of 1.4 mm, and used to infuse nerve growth factor. Under local anesthesia and using the stereotactic computed tomographic technique of Leksell and Jernberg,[31] coordinates for a target located centrally in the left putamen were determined. This target point was located 15-mm anterior and 5-mm superior to the midpoint of the intercommissural line, and 23-mm from the midsagittal plane (Fig 2).

Under general neuroleptic anesthesia, a burr hole was made in the left frontal region, close to the coronal suture. Via a few small skin incisions, the nerve growth factor–filled catheter was pulled from the region of the manubrium sterni to the burr hole (Fig 2). Using stereotactic technique, it was introduced to the predetermined target using a special cannulation technique[32] and secured to the edge of the burr hole. The incisions were temporarily sutured. The catheter was equipped with fine holes at the end and a sealed radio-opaque tip. The indwelling soft catheter was designed to compensate for any normal minor horizontal movements of the brain parenchyma relative to the skull. The assembly had a dead space of 0.8 mL and was filled with nerve growth factor solution. Because the effects of nerve growth factor were unknown, the left putamen was chosen for the target because the patient was left-handed. There were no preoperative side differences in her parkinsonian symptoms to contraindicate this decision.

The patient was next placed in the left lateral position. The left adrenal gland was chosen because it has a longer vein, which simplifies the adrenalectomy. The gland was removed using a lateral extraperitoneal approach, removing part of the 12th rib. A small rim of cortical tissue was left in situ. Since it has been shown that patients can maintain basal corticosteroid production from a resected gland,[33] this precaution should enable future removal of the right adrenal gland, if desirable. The adrenal gland was sectioned into slices from which medullary tissue was prepared. Pieces (1 to 2 mm^3) of adrenal medullary tissue, carefully freed from any adjacent cortical tissue, were collected in a solution consisting of 4 mL of

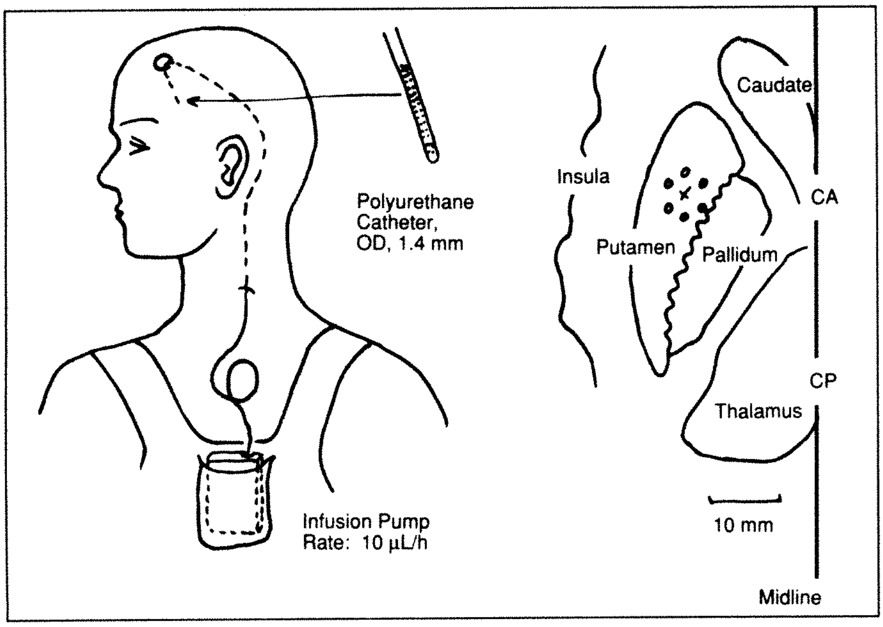

Fig 2.—At the right is depicted a schematic drawing of a horizontal section through the central nuclear complex of the human brain. The spatial arrangement in the putamen of the six adrenal medullary grafts (circles) and the nerve growth factor catheter (cross) is shown. The drawing to the left shows the design used for chronic intraputaminal infusion of nerve growth factor. The microinfusion pump for long-term nerve growth factor administration is percutaneously connected to a catheter, the tip of which is positioned in the putamen. OD indicates outside diameter; CA, anterior commissure; CP, posterior commissure.

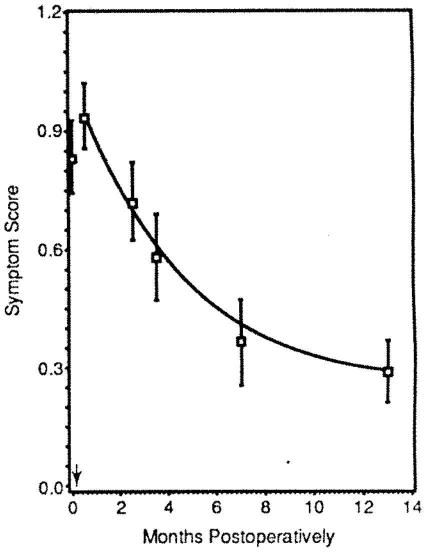

Fig 3.—Parkinsonian scores preoperatively and postoperatively. Each point represents the averaged scores from hourly scoring during a minimum of 5-day periods at the indicated times. The arrow indicates the time of operation and initiation of infusion of nerve growth factor. The mean scores are seen to decline exponentially postoperatively. Using approximate Wald tests, the curve is significantly lower than the preoperative mean 3.5 through 13 months postoperatively.

Ringer's solution with glucose, 2 mL of citrate plasma from the patient, and 0.5 mL of nerve growth factor solution containing 600 μg/mL of nerve growth factor. The implantation instrument previously described[10] was loaded six times with 13 to 15 pieces of adrenal medullary tissue in the nerve growth factor–containing solution. The pieces were deposited using six needle tracks, equidistant (3 to 4 mm) from the central implanted nerve growth factor–infusion cannula (Fig 2). The first implant was inserted 50 minutes after removing the adrenal gland, and the last, 114 minutes after adrenalectomy. Altogether, an estimated 85% of all available chromaffin tissue in the extirpated gland was used for implantation.

The pump (MiniMed Technologies, Sylmar, Calif) was connected to the tubing and affixed to the patient. Pumping at a rate of 10 μL/h was initiated 1.5 hours after the first implantation of adrenal medullary tissue. The infusion was carried out for 23 days by replacing the nerve growth factor–containing syringes every fourth to fifth day. The indwelling cannula and the subcutaneous tubing were removed 25 days after surgery.

Clinical Assessments

Rigidity/hypokinesia was evaluated using a scoring system for parkinsonian symptoms with the patient relaxed in the supine position, in a standing position, and walking, using the following scores: 0, absent; 1, slight; 2, moderate; and 3, severe. A similar scoring system was used to rate drug-induced hyperkinesia. In addition to the period before and after surgery (6 weeks), the patient was hospitalized and the scoring was carried out for approximately 5-day periods at intervals preoperatively and postoperatively. The scorings were made around the clock on the hour from 7 or 8 AM to 9 PM without interfering with the medication, generating a total of some 600 scores for symptoms and an equal number of scores for hyperkinesia at the time points indicated in Fig 3. The same team of experienced personnel (two physicians and four nurses) was responsible for all of the scoring throughout the study. The interrater reliability was checked operationally and repeatedly and found to be high. Tremor was observed only to a minor degree and intermittently in this patient, and was, therefore, not recorded. Gait was evaluated as the number of steps and time needed to walk 7 m and return. The number of steps needed to turn around was also recorded. The Mini-Mental State test[34] was used to evaluate possible signs of cognitive dysfunction on several occasions preoperatively and postoperatively.

Evoked Potentials

To provide information on central motor and sensory functions, averaged readiness and auditory evoked EEG potentials were recorded. The motor readiness potential consists of several components, one of which is a slow negative wave beginning about 1 second before a voluntary movement. This component is diminished in unmedicated patients with Parkinson's disease[35] and increases during the on-phase of levodopa treatment.[36] We have previously used the readiness potential to monitor effects of both adrenal medullary[12] and human fetal dopamine neuron[17] grafts to patients with Parkinson's disease.

Readiness and auditory evoked potentials were recorded with the patient in off-phase. For such recordings, the patient was instructed not to take any medication after 9 PM the night before, and the recordings were carried out the next morning prior to any medication. To record motor readiness potentials, the patient was supine and the torso was elevated 45°. A telegraph key was placed under one hand, and the patient was instructed to press the key slowly, self-pacing the movement at about 4-second intervals. The key was constructed so that a pulse was generated at the initiation of movement. Recordings were made at C_z, F_3, F_4, and 1-cm anterior to C_3 and C_4 in the International 10-20 System, referenced to the ipsilateral ear. A bipolar electro-oculographic recording was made from the lateral canthus and the superior orbit of the right eye. A bipolar electromyographic recording was made over the forearm flexor muscle group that contracted when the key was pressed. Electrical activity was amplified and filtered (0.01 to 30 Hz); the waveforms were digitized at 100 Hz and analyzed by computer. Fifty artifact-free trials were obtained for keypresses with each hand. The resulting averages were digitally smoothed by averaging data from each of three adjacent points. The motor readiness potential was quantified as the voltage 0.5 second before the movement, relative to the average potential 1.0 to 2.0 seconds before the movement.

Auditory evoked potentials were recorded from a vertex electrode employing a conditioning-testing paradigm. This paradigm uses paired stimuli to assess the gating of responses to sensory input. Subjects normally suppress the response to the second stimulus because of gating mechanisms activated during response to the first. The P50 wave is used as the target response because it is less affected by changes in the subject's attention. Decrease in suppression of the P50 wave with the conditioning-testing paradigm has been linked to increased catecholaminergic neurotransmission.[37] Such decreased suppression was observed following adrenal grafts in a previously studied set of patients.[12] For further details of the recording methods, refer to the article by Adler et al.[38]

Statistics

Because of the variability of symptom intensity during the day, the clinical scores were analyzed by a two-way analysis of variance, with months before or after the operation and time of day as independent variables. The method of Grizzle et al[39] was used for the nonparametric analysis of categorical rating scores. The large numbers of observations for several of the measurements make possible meaningful analyses of the significance of change in this individual patient but do not allow statistical prediction about other future subjects.

RESULTS

Surgery

The operation was performed in May 1989 without complications. The patient was under general anesthesia for a total of 6 hours. There were no major changes in blood pressure during either adrenal removal or chromaffin tissue implantation in the brain. The patient woke up promptly after discontinuation of anesthesia. A postoperative computed tomographic scan showed the tip of the infusion catheter to be located correctly in the predetermined position in the center portion of the left medioputamen.

A computed tomographic scan 9 days after surgery showed that the tip of the nerve growth factor catheter had become dislocated 2.5-cm upward in the cannula tract sometime after the initial postoperative scan. Most probably, this was caused by hyperkinetic movements of the head and neck pulling on the catheter. The catheter was repositioned using stereotactic surgery under local anesthesia 12 days postoperatively. The repositioning was uneventful, and computed tomographic scans on the day of repositioning and several times afterward showed the tip of the catheter to be correctly positioned. Initially, there were slight signs of corticospinal tract dysfunction, consisting of an intermittently positive Babinski sign on the right side, but no paresis. This was most probably due to an edema, which developed around the catheter in the frontal lobe and which resolved during the next 2 to 3 months.

Postoperative Clinical Course

In the evening following surgery, deprived of medication since the night before, the patient was awake and mentally alert. There were clear-cut lateralized changes in her arms, such that there was only slight rigidity in her right arm, while her left arm was rigid in a cogwheel pattern. Such a lateralized difference did not exist before surgery. No pareses were noted. It was possible to begin reinstating her medication in the evening and, beginning the next day, to give her full medication.

The lateralized difference in rigidity was prominent during the first 14 postoperative days. Both the right arm and the right leg could be passively moved without rigidity, while cogwheel phenomena and rigidity were noticed on the left side. Notably, she had almost no hyperkinetic movements during this time. She was also more mobile in off than prior to surgery and was able to walk slowly.

The hyperkinesia gradually returned, beginning during the second postoperative month. Seven months postoperatively, it was decided to begin administering the selective monoamine oxidase–B inhibitor selegiline (Eldepryl, Farmos Group, Helsinki, Finland) to the patient, because of increasing evidence for its efficacy in other patients with Parkinson's disease. The effect of selegiline was initially dramatic, leading to a marked improvement of parkinsonian symptoms. Four months later, the improvement was less dramatic. When selegiline therapy was initiated, the levodopa medication was lowered by 350 mg/d because of increased hyperkinesia. Otherwise, no changes were made in the patient's medications, to permit comparisons between the preoperative and postoperative states. The Mini-Mental tests carried out on several occasions preoperatively and postoperatively did not show any cognitive dysfunction.

Ratings of Parkinsonian Symptoms

Analysis of variance of the global rating of rigidity/hyperkinesia showed a strongly significant ($P=.01$) effect of month of observation, which indicates that the patient's major parkinsonian symptoms had decreased following the operation (Fig 3). Hour of observation during the day was a nonsignificant factor ($P=.4$), and there was no interaction between hour and month.

The downward trend in Fig 3 was examined more closely. The differences between the six monthly means adjusted for time of day can be described in terms of a preoperative mean score, M, of 0.831 (±0.215) and a postoperative exponential decay curve, where

$$\text{Score} = a + (b - a)\, exp\, [(-0.693\ \text{Months} - 0.5)/c]$$

where $a = 0.261$ (±0.172) is the lower asymptote to which the score seems to be decaying, $b = 0.960$ (±0.087) is the maximum value observed 1 month after the operation, and $c = 3.023$ (±0.195) is the number of months after the operation at which the symptom score curve decayed halfway between the maximum at 0.5 month and the minimum M. The variables a, b, and c are all significantly different from zero at the .05 level. The fit of the preoperative and postoperative models are depicted in Fig 3. Using approximate Wald tests as discussed by Seber and Wild,[40] the curve is significantly lower ($P<.05$) than the preoperative mean 3.5 through 13 months after surgery.

Walking Tests

The time and number of steps needed to walk 7 m, make a 180° turn and return were repeatedly recorded preoperatively and postoperatively. As illustrated in Table 1, it appeared as if the time needed to carry out the test in off was decreased after the operation, while the number of steps did not change. There was a tendency for the number of steps required to make the 180° turn to decrease and remain less than preoperatively at the 13-month postoperative time point.

Pegboard Tests

The test records the time needed to place pegs in a board and, thus, is mainly a measurement of fine-motor control. As shown in Table 2, there was some decrease of the time to complete the test in off 7 and 13 months postoperatively, while there was a slight increase in the time to complete the test in on. No consistent changes were noted 2 to 3 months postoperatively. No major side effect differences in this test were observed.

Table 2.—Pegboard Test*

State	Side	Preoperative	Postoperative, mo 2-3	7	13
On	Right	74 ± 9 (17)	76 ± 5 (15)	88 ± 6 (6)	78 ± 16 (7)

	Left	100 ± 22 (9)	82 ± 16 (7)	89 ± 24 (3)	78 ± 10 (5)

*Time in seconds ± SD (No. of observations).

Readiness and Auditory Evoked Potentials

Recordings carried out in off at four occasions prior to surgery (2.5 months, 1.3 months, 0.7 months, and 3 days) showed the diminished readiness potential amplitude previously reported for unmedicated parkinsonian patients (Fig 4). Recordings made in the immediate postoperative period (6, 21, and 29 days) showed the marked increase in readiness potential amplitude seen in other patients who have received adrenal grafts.[12] The increase was present over both hemispheres and with movements of both the left and right hand. This increase was not noticeable in the 2.5-month postoperative recording. In the final recording, performed 13 months postoperatively, the readiness potential was moderately increased, compared with the preoperative records. The increase was greater over the left hemisphere and could only be elicited with movements of the right hand. These data are consistent with an improvement in function, localized to the left hemisphere. The time course of changes of the amplitude of the readiness potential recorded over the left hemisphere, as elicited by movements of the right hand, is illustrated in Fig 4. When the degree of readiness potential negativity was mapped over the patient's head, there was no side difference preoperatively. Thirteen months after surgery, there was clearly more negativity over the operated (left) than over the nonoperated hemisphere (Fig 4).

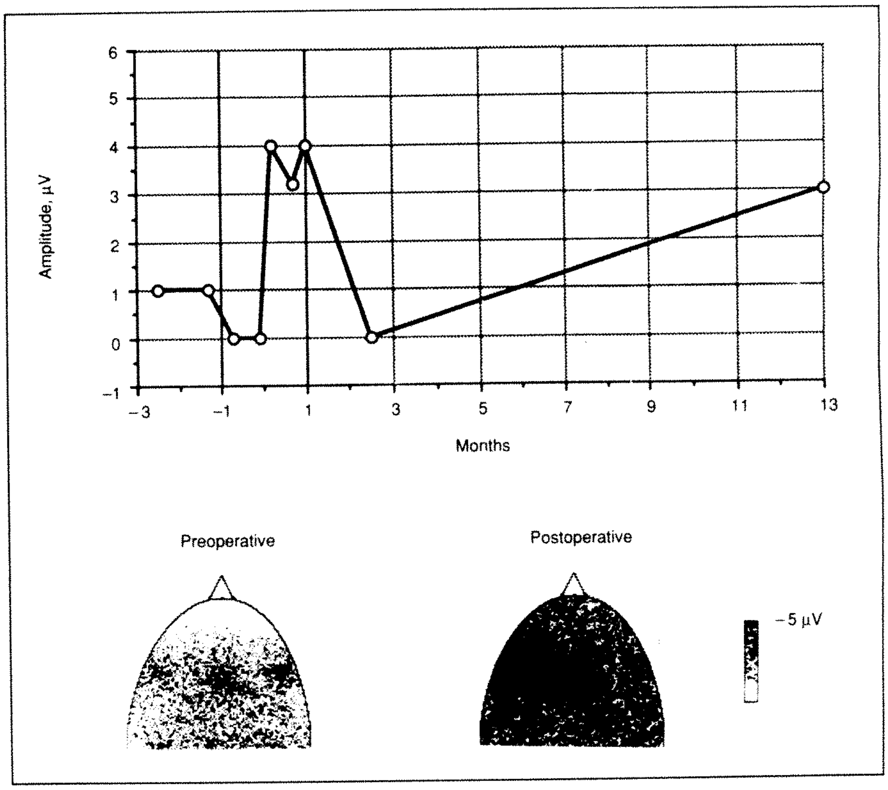

Fig 4.—Top, Readiness potentials recorded preoperatively and postoperatively from the left (operated) hemisphere, for right-hand movements. The potential is very low or absent at the four preoperative recordings and markedly increased during the first postoperative month. Although absent again at 2.5 months postoperatively, it is well above the preoperative average 13 months postoperatively. Below, Distribution maps of readiness potential negativity preoperatively (left) and 13 months postoperatively (right). Postoperatively, movements of the right hand cause a lateralized increase of negativity over the left (implanted) hemisphere.

The auditory evoked P50 potential showed normal amplitude, latency, and suppression in the preoperative period. A transient decrease in suppression in the first 3 postoperative months was noted, similar to that seen in the previously studied patients with adrenal grafts.[12] At the 13-month postoperative recording, the auditory evoked potentials were normal.

Nerve Growth Factor: Stability and Immunization Tests

Bioassay measurements of nerve growth factor activity in fluid remaining in used syringes as well as in the tubing, which was recovered when removing the tube and indwelling catheter, showed that storage at body temperature for several days did not decrease nerve growth factor activity at all. Measurements of the possible presence of anti–nerve growth factor antibodies in the patient's blood showed no significant differences between one sample taken preoperatively and three samples taken postoperatively. The largest difference between any one of the four samples was a factor of 1.8, which should be compared with a factor of approximately 10 000 between preimmune and postimmune serum samples typically seen when a rabbit is immunized with nerve growth factor.

COMMENT

This report is, to the best of our knowledge, the first documentation of administration of nerve growth factor to the human brain. A relatively large amount of purified mouse β–nerve growth factor was continuously infused into the putamen over a 3.5-week period. As far as our data indicate, this did not cause any negative effects either acutely or chronically. We, therefore, postulate that nerve growth factor administration in this way is a safe procedure.

The use of mouse nerve growth factor, currently the only nerve growth factor available in large enough quantities for such a trial, is based on the high degree of homology between nerve growth factor from various species. Thus, the amino acid sequence homology between mouse[41] and human[42,43] nerve growth factor is 90%. Of 118 amino acids, only 12 are different. Thus, mouse salivary β-nerve growth factor is equipotent in stimulating neurons from chick, mouse, and man. Mouse nerve growth factor has also been shown to stimulate human chromaffin cells in tissue culture.[44] By analogy, the homology between porcine and human insulin is 94%, a degree of similarity allowing porcine insulin to be used as a drug for human diabetes. Moreover, the use of human recombinant nerve growth factor, although preferable if it can be produced in quantity and purified, is no guarantee against immunization. For example, mice can be immunized with mouse nerve growth factor using the appropriate protocols (such as Freund's adjuvant) to generate good-quality anti–nerve growth factor antibodies.[45] The likelihood of immunization to a foreign or rare protein should, however, be much lower if the protein is injected into brain tissue. Indeed, an ultrasensitive immunoassay[29] could not detect signs of immunization following nerve growth factor infusion in the present case. Finally, in terms of the safety of the procedure, it is worth noting that adult laboratory animals in which very high titers of anti–nerve growth factor antibodies have been induced have no overt signs of disease.

It is well known that adult chromaffin cells in rodents can transform toward neuronal phenotypes following grafting[46] and that this transformation is induced by nerve growth factor.[20] Although such neuronal transformation does not appear to be necessary for adrenal grafts to have some beneficial effects in the rat model of Parkinson's disease (unilaterally 6-hydroxydopamine–denervated striatum),[20,47] nerve growth factor markedly increases the number of surviving chromaffin cells, induces neuronal transformation and nerve fiber production (see also reference 48), and increases the functional effects of the chromaffin grafts.[20] Such marked effects of exogenous nerve growth factor are probably best explained by the fact that the striatum normally contains very low levels of both nerve growth factor messenger RNA[49] and endogenous nerve growth factor protein.[50] The results with nerve growth factor–supported grafts seen in laboratory animals,[20] including more recent data suggesting that aged chromaffin tissue also responds to nerve growth factor[22] as well as a more detailed analysis of the nerve cell transformation of nerve growth factor–treated chromaffin cells,[21] form the basis for the present clinical study. Without nerve growth factor, the positive effects seen in patients given chromaffin tissue into the putamen and caudate appear to be approximately of the same magnitude and duration in man[12] as it is in rat.[20] Indeed, a chromaffin autograft, recovered postmortem 4 months after implantation into a patient with Parkinson's disease, revealed modest survival and scant tyrosine hydroxylase immunoreactivity paralleled by little clinical benefit.[51] In marked contrast, nerve growth factor support leads to more pronounced and long-lasting effects on motor behavior in both rats[48] and, as described here, man.

It has recently been suggested[52] that the positive effects of transplantation of fetal and chromaffin cells to dopamine-lesioned striata in rodents,[7-9] nonhuman primates,[53,54] and man[10,12,13,17] are due to nonspecific actions of the graft surgery. In terms of stereotactic implantations to man, the data in this communication argue against such a suggestion, since the addition of nerve growth factor changed the functional outcome after stereotactic implantations of chromaffin cells, compared with earlier results using the same surgical techniques.

The positive long-term changes in this patient are best documented in the statistical analysis of the global symptom scores. There were other indicators of the presence of longer-term changes, which were different in some regards from the effects observed in patients who had received adrenal grafts without nerve growth factor. Thus, the readiness potentials indicate long-lasting effects and suggest improvements of function over the left hemisphere. The auditory evoked potentials showed differences as well. The early postoperative loss of suppression of the P50 wave, seen in all of the patients who underwent an adrenal graft, including this one, suggests a massive release of catecholamines. The ensuing normalization of suppression, observed in this patient as well as in the patients who received fetal mesencephalic grafts, suggests that release is limited to the basal ganglia, perhaps because of more localized release and reuptake from newly formed nerve fiber terminals. It is also interesting that the patient showed an unusually positive response when selegiline treatment was initiated. This suggests that monoamine oxidase–B inhibition may increase the availability of catecholamines released by the chromaffin cell grafts.

Although the patient herself has not experienced any major improvements in activities of daily living, the significant long-term decrease in parkinsonian symptoms and the apparent absence of negative effects of nerve growth factor infusion described in this report suggest that chromaffin autografts, supported by temporary nerve growth factor infusion, should be investigated further.

In comparison with the open neurosurgical approach introduced by Madrazo et al,[13] stereotactic implantation appears to have several advantages. First and foremost, it enables implantation into the putamen. Second, it is less traumatic and, therefore, should carry fewer risks for the patient. In terms of efficacy, it is too early to draw any firm conclusions, but it is clear from the relatively large number of patients now treated by adrenal autografts implanted into the caudate[55-60] that the initially reported dramatic and sustained improvements have not been replicated[59,60] and that there is significant morbidity and/or mortality (eg, reference 58).

In comparison with implantation of fetal substantia nigra neurons obtained from aborted fetuses,[17,18] currently also under clinical trial in Parkinson's disease, the chromaffin alternative offers some advantages. First, there is no need to coordinate the grafting activities with the procurement of fetal brain tissue. Second, immunosuppression, currently believed by several groups to be necessary with fetal grafts,[17] is not needed with autografts. Third, it is possible that grafted dopamine neurons might be more susceptible to the disease process than would the grafted chromaffin cells. Several other factors that may be of potential importance also differ between the two procedures. The mesencephalic fetal brain tissue grafts by necessity contain several types of immature neurons other than dopamine neurons, as well as glial precursor cells. On the other hand, chromaffin cells secrete only small amounts of dopamine and larger amounts of noradrenaline. While, in the absence of high local concentrations of corticosteroids and after nerve growth factor–induced transformation, chromaffin cells may cease to produce adrenaline, it is not known to what extent other substances normally secreted by chromaffin cells (such as endorphins) are still synthesized, released, and influence the host brain.

Based mainly on studies of tyrosine hydroxylase immunoreactivity following dopaminergic lesions with methylphenyltetrahydropyridine (ie, MPTP), it has been suggested that adrenal medullary grafts may exert a trophic influence on remaining host dopamine terminals.[61] A similar effect has been described also in primates[62] and cannot be excluded in the present case. However, it does not readily explain the difference in duration of effects between our present nerve growth factor–supported case and our previous adrenal medullary implantations not supported by nerve growth factor. Indeed, studies in 60HDA-denervated rats that are so completely denervated that dopaminergic sprouting cannot occur prove that nerve growth factor–supported adrenal medullary grafts *can* reduce turning behavior without having to assume trophic effects and that these reductions are correlated to the amount of surviving cells and nerve fibers formed by the grafted cells.[48] Clearly, further work is needed to determine the relative role of directly graft-derived catecholamines vs graft-induced trophic effects on host neurons.

As presented elsewhere recently,[19] there are several ways in which the chromaffin autograft procedure might be improved in the future. Perhaps most important, it may become possible to increase the number of cells by treating dissociated chromaffin cells in culture with basic or acidic fibroblast growth factor in the presence of dexamethasone. This procedure induces mitosis, neuronal differentiation, and nerve growth factor dependence in immature rat chromaffin cells[63,64] and can also induce division in adult chromaffin cells. Thus, one could envision a two-step procedure in which chromaffin tissue is first removed from the patient. Cells would then be grown in culture to appropriate amounts and subsequently grafted back to the basal ganglia of the patient in the form of suspensions.

The recent discovery that nerve growth factor is a member of a family of closely related factors including brain-derived neurotrophic factor (ie, BDNF[65]) and neurotropin-3/hippocampal-derived neurotrophic factor (ie, NT-3/HDNF[66-69]), which are all synthesized by neurons in the brain,[70-72] opens new possibilities for treatments with combinations of grafts and/or growth factors in neurological disease. The present data are particularly relevant to Alzheimer's senile dementia, since they suggest that nerve growth factor might be safely administered for extended periods of time to the human brain, a strategy recently considered also for Alzheimer's disease (see, eg, Goedert et al[73]). In the latter case, based on animal experimentation, it has been speculated that nerve growth factor might counteract cholinergic deficits by exerting trophic effects on the ascending cholinergic projections to the hippocampus and cortex cerebri (see reference 74).

In conclusion, we have shown long-lasting positive effects of adrenal autografts supported initially by nerve growth factor infusion in a patient with severe Parkinson's disease. Although grafting strategies in Parkinson's disease only aim at compensating for the neuronal losses once they have occurred, they remain potentially important approaches for patients who have already lost substantia nigra neurons. Obviously, ways of preventing the degeneration of dopamine neurons, such as the current trials with monoamine oxidase-B inhibition or the identification of specific dopaminotropic factors, would be extremely important therapies once shown to be clinically effective. These complexities notwithstanding, among the alternative transplantation strategies, we believe that chromaffin autografts, placed stereotactically in the basal ganglia and supported by temporary nerve growth factor infusion, merits further scientific exploration on the basis of the present findings.

This work was supported by the Swedish Medical Research Council (Stockholm), the Swedish Natural Science Research Council (Stockholm), Magnus Bergvalls Stiftelse, Karolinska Institutets Fonder, Loo and Hans Ostermans Fond, Kung Gustav V and Drottning Victorias Stiftelse, The Miami (Fla) Project Foundation, the Department of Veterans Affairs, Washington, DC, and US Public Health Service, Bethesda, Md, grants NS09199, MH38321, and AG04418. Support from Mr and Mrs Philip Hoffer and the Mathers Foundation is also gratefully acknowledged. We thank Hans Karlsson, Carnegie Medicine, Stockholm, Sweden, for expert help constructing the tubing and infusion device and controlling the programmable infusion pump. Gary Zerbe, PhD, Department of Biostatistics, Medical Center, University of Colorado, Denver, is gratefully acknowledged for carrying out the statistical analysis. We thank Ida Engqvist for expert editing and secretarial support. We also wish to thank Jan-Eric Wedlund, MD, at Stora Sköndal Hospital for helpful information about the patient before and after surgery, as well as anesthesiologist Kristina StÅnge. Bo Molin, Stine Söderström, and Annika Kylberg are gratefully acknowledged for nerve growth factor preparations, purifications, and assays, and Mats Sternhag and Görel Caneman, for carrying out the walking and pegboard tests.

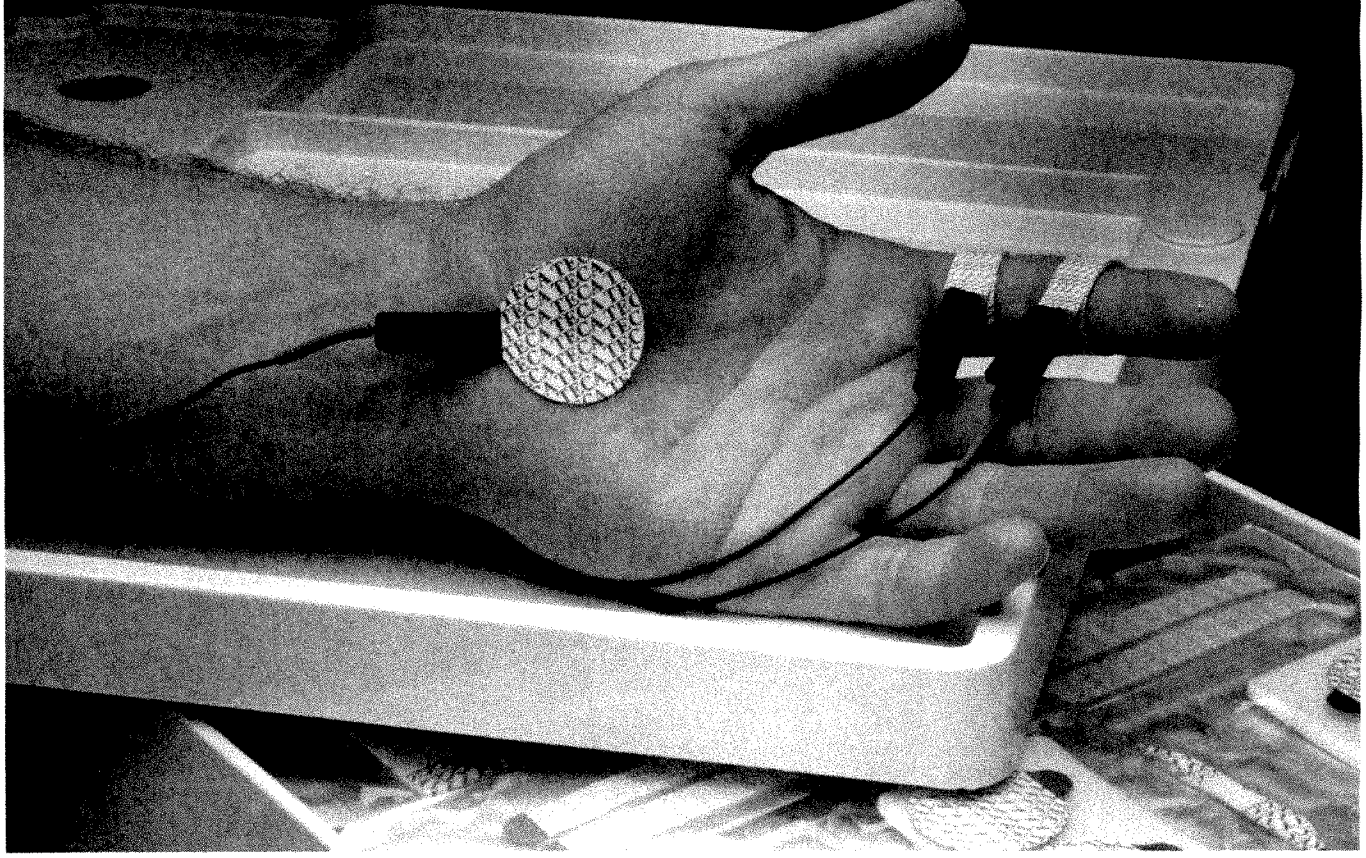
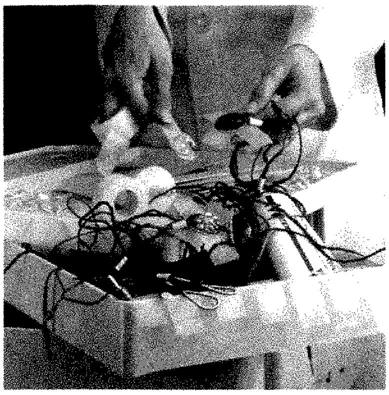
Choose The System That Promises Consistency...



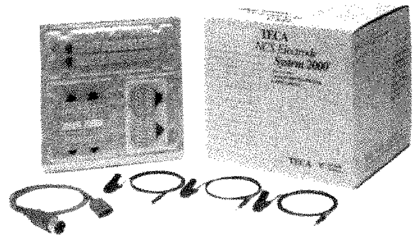
And Sticks To It.



The TECA NCS Electrode System 2000™.

The most advanced technology for NCS is also the simplest. The most accurate. And the most consistent. The TECA NCS Electrode System 2000. The world's first integrated electrode system designed *exclusively* for nerve conduction by the leading manufacturer of neurodiagnostic accessories, TECA Corporation.

The TECA system utilizes self-adhesive and self-conductive disc, digital ring and ground electrodes for efficient application. No gels. No tape. No mess. A shielded cable and high quality materials enhance recording signals and deliver consistent, low-noise results every time. *TECA guarantees it. That's our promise.*



Try TECA NCS Electrode System 2000. Order the Introductory Evaluation Kit (Catalog #2008), containing everything you need to complete four patient exams. Just call Accessories Customer Service at 1-800-GET-TECA. Use the system once, and you'll stick with it.

Prednisone in Duchenne Dystrophy

A Randomized, Controlled Trial Defining the Time Course and Dose Response

Robert C. Griggs, MD; Richard T. Moxley III, MD; Jerry R. Mendell, MD;
Gerald M. Fenichel, MD; Michael H. Brooke, MD; Alan Pestronk, MD;
J. Philip Miller; and the Clinical Investigation of Duchenne Dystrophy Group

• A randomized, controlled trial of daily prednisone was conducted in 99 boys (aged 5 to 15 years) with Duchenne dystrophy to define the time course of improvement and the dose response to treatment. Prednisone at 0.3 mg/kg (n = 33), prednisone at 0.75 mg/kg (n = 34), and placebo (n = 32) were administered for 6 months. Patients were examined using manual muscle and myometry testing, timed functional testing, pulmonary function testing, and laboratory measurements at 10 days, 1 month, 2 months, 3 months, and 6 months of treatment. Boys treated with prednisone had stronger average muscle strength scores, than did boys treated with placebo as early as 10 days after starting therapy. At the 3-month visit, the boys in the group given 0.75 mg/kg of prednisone were significantly stronger than those in the group given 0.3 mg/kg of prednisone, indicating a dose response. At 6 months, significant side effects occurred in the group treated with 0.75 mg/kg of prednisone, including weight gain, cushingoid appearance, and excessive hair growth. Only weight gain was observed in the group taking prednisone at a dose of 0.3 mg/kg. Importantly, no side effects were evident at 10 days or 1 month of treatment, despite improvement in muscle strength and function. We conclude that prednisone produces a rapid increase in muscle strength in patients with Duchenne dystrophy and that this improvement is maximal at a prednisone dosage of 0.75 mg/kg or less.

(*Arch Neurol.* 1991;48:383-388)

Duchenne muscular dystrophy is an X-linked recessive disorder that results from a gene defect causing a deficiency of the cytoskeletal protein, dystrophin.[1] The potential replacement of dystrophin by transfer of normal myoblasts is under study,[2-4] and the possibility of direct gene replacement has also been considered.[5] However, only one form of treatment has been shown to alter the course of the disease. In a recent double-blind, randomized, controlled trial, prednisone treatment in the dosage of 0.75 mg/kg per day or 1.5 mg/kg per day resulted in a significant improvement in strength and function of patients with Duchenne dystrophy,[6] confirming our own[7] and other previous observations.[8] The present study was designed to obtain additional data on the effectiveness of prednisone in Duchenne dystrophy; determine the dose response for prednisone by comparing a dosage of 0.75 mg/kg with a smaller one, 0.3 mg/kg; determine the time course of improvement by performing earlier tests of strength; and provide additional data on side effects of prednisone.

PATIENTS AND METHODS

Patients

A total of 99 patients, 5 to 15 years old, with Duchenne dystrophy, as defined in previous investigations,[9-11] were studied at the five collaborating institutions (University of Alberta, Edmonton; University of Rochester (NY); The Ohio State University, Columbus; Washington University, St Louis, Mo; and Vanderbilt University, Nashville, Tenn). The Institutional Review Board at each center approved the protocol. After informed consent was obtained from the parents in the presence of an auditor witness, patients were randomized to one of three treatment groups: placebo (n = 32), 0.3 mg/kg of prednisone (n = 33), and 0.75 mg/kg of prednisone (n = 34). Prednisone dose was rounded off to the nearest 5 mg. The study was a 6-month, double-blind trial.

Medication

Gelatin capsules (No. 3 Eli Lily, Indianapolis, Ind) containing powdered prednisone (Spectrum, Gardena, Calif) or placebo were prepared and dispensed from the pharmacy at the University of Rochester (NY), Strong Memorial Hospital. Placebo was administered as a capsule that weighed 240 mg and contained powdered lactose. Prednisone was prepared in a capsule containing the appropriate dose and sufficient lactose to give a capsule that weighed 240 mg. After the initial evaluation, each patient was provided with a 6-month supply of medication. A family member dispensed one capsule per day to the patient at breakfast. Compliance was evaluated by weighing the bottle of medication initially and at each return visit.

Study Protocol

Patients were admitted to the Clinical Research Center before the start of treatment. During the initial admission to the Clinical Research Center, clinical evaluations were made on 2 consecutive days, after which prednisone was started. Patients were reassessed as outpatients at 10 days, 1 month, 2 months, 3 months, and 6 months. Each outpatient visit included independent clinical and side-effect evaluations obtained by the clinical evaluator and principal investigator, respectively.

Clinical Evaluation

Clinical evaluators tested patients' muscle strength by manual muscle testing of 34 muscle groups, graded according to an expanded 10-point scale, based on the Medical Research Council methods.[12] A score for average muscle strength was derived from these measurements.[11] Muscle strength was also evaluated with a Penney and Giles hand-held myometer,[13] testing the strength at the shoulder abductors, elbow flexors and extensors, and the hip abductors on the right side. The average at the make and break readings (the maximum strength exerted before giving way) was used for analysis. Muscle function was evaluated by timed functional testing, including measurement of the time needed to rise to a standing position from a lying position on the floor, to climb four standard-size steps, and to travel 30 feet (9 m) as rapidly as possible. An overall functional grade was assigned for both the upper and lower extremities. The maximum hand-held weight that could be lifted with the patient sitting was assessed. Pulmonary function tests included measurements of forced vital capacity, maximum voluntary ventilation, and maximal expiratory pressure. All measures except the myometer strength testing were performed as in our previous studies.[9,11]

Laboratory Evaluation

Blood specimens for creatine kinase evaluation were obtained at baseline and after 6 months of treatment, and measurements were performed in a central laboratory.[6]

Blood tests for safety monitoring were performed before prednisone administration and at 6 months, including a complete blood cell count and measurement of serum sodium, potassium, chloride, calcium, phosphate, glucose, carbon dioxide, serum urea, nitrogen, creatinine, bilirubin, alkaline phosphatase, alanine aminotransferase, and aspartate aminotransferase levels.

Side Effects

Patients were examined and parents were interviewed for side effects at both visits prior to initiating treatment and at 1, 2, 3, and 6 months of treatment. These evaluations were performed by the principal investigator physician and did not take place in the presence of clinical evaluators testing patients and recording data. The evaluation included assessment for cataracts, edema, cosmetic, behavioral, and other potential side effects of prednisone therapy. Urinary dipstick for glucose was obtained at each visit. Height, weight, pulse, blood pressure, and temperature were obtained at the same frequency by the Clinical Research Centers' nursing staff. Blood studies were obtained as described above. In addition, the occurrence of all intercurrent events, including infections, coincidental illness and medications, surgery, or other events, were monitored at each visit.

Prior to treatment and at each follow-up visit, patients were instructed to follow a diet low in sodium and simple sugars. Vigorous counseling by the Clinical Research Centers' dieticians was provided to both patients and parents of boys gaining weight. All patients were instructed to take 0.3 g of calcium carbonate with each meal.

Statistical Analysis

At the initial visit to the Clinical Research Center, baseline values were obtained by computing the mean for each variable in each patient. At initial visits, statistical comparisons between the treatment groups were evaluated with use of one-way analysis of variance, and, at subsequent visits, with use of analysis of covariance, in which the value for a treatment group served as the classification variable and the corresponding baseline value for that measure as a covariate. On the basis of our previous experience with the natural history of Duchenne dystrophy, we used natural-logarithm transformations of certain values, when necessary, to control for heteroscedasticity. Average muscle strength was chosen a priori as the primary measure of treatment efficacy. The primary test of each measure was a determination of the differences between the least-square mean for the placebo group and the mean for the two prednisone groups at each visit. Auxiliary assessments included tests of the differences between the placebo group and each prednisone group and the differences between the two prednisone groups. Least-square means (which adjust the treatment-group means for differences in baseline values) were computed for all measures. The *P* values reported for all tests of significance are two sided. Computations were performed with SAS GLM type III sums of squares.[14] The variables were evaluated individually, with no correction for multiple comparisons. Such correction would not materially affect the conclusions, since the uncorrected *P* values were very small. Sample size in this study was sufficient to achieve a power of 0.7 to detect arrest of disease progression within 6 months.

The analysis of the significance of differences in the prevalence of side effects was assessed by a categorical model fit with Proc CATMOD.[14] In the analysis of weight change, a cumulative logit was used as the dependent

variable. For other side effects, the default logit response was employed. Contrasts were computed as for the measures of efficacy. The power of this study to detect differences in side effects between groups is inadequate except for major changes.

RESULTS

Baseline Assessments

There were no significant differences between the three patient groups in any baseline values for age, muscle strength score, leg function grade, timed functional testing, ability to lift weights, pulmonary function, or creatine kinase concentration (Table 1). (For certain patients, disability precluded testing of a specific function.)

Results of Treatment

At 10 days, the average muscle strength of the low-dose (5.87) and high-dose (5.88) groups was significantly greater ($P = .05$) than that for the placebo-treated group (5.78) (Table 2). This improvement increased at 1 month and then reached a plateau that persisted until 6 months (Fig 1 and Table 2) and contrasted with the placebo group that became steadily weaker. The increase in average muscle strength above baseline at 6 months was similar to that observed at 3 months for both patient groups. The higher dose of prednisone (0.75 mg/kg) produced a greater increase in muscle strength at each time point than did the low dose (0.3 mg/kg), although the difference did not become statistically significant until 3 months ($P = .02$) (Fig 1). The placebo group declined in muscle strength similarly to the natural history rate of decline previously observed in Duchenne dystrophy.[7,9]

At 6 months, the high-dose and low-dose prednisone groups were significantly improved compared with placebo group in leg function grade, timed functions, lifting weights, and forced vital capacity. The improvement was statistically greater in the high-dose prednisone group for most measures (Table 3). In the low-dose prednisone group, some measures did not change when compared with placebo (Table 3).

Side Effects

The incidence of side effects in the three study groups is indicated in Table 4. Patients taking prednisone at 0.75 mg/kg per day had a significant incidence of cushingoid appearance (71%), excessive hair growth (41%), and increased appetite (68%). Patients taking 0.3 mg/kg of prednisone per day did not have any side effects that were present to a significantly greater extent than those reported in the placebo group. There was a trend for patients taking 0.3 mg/kg of prednisone daily to have an increased appetite ($P = .10$).

Significant weight gain occurred in both prednisone-treated groups (Table 5; Fig 2), and, although a smaller percentage of patients gained over 20% above baseline on the 0.3-mg/kg dosage, the difference was not significant between groups (0.3 mg of prednisone, 11%; 0.75 mg of prednisone, 31%; $P = .18$). Neither group of patients gained significantly more than placebo-treated patients until 2 months of treatment (Fig 2).

COMMENT

This study confirms our previous, controlled, double-blind, therapeutic trial showing that prednisone produces a significant *increase* in muscle strength, pulmonary function, and functional ability in patients with Duchenne dystrophy. In addition, the present study helps to define the minimum prednisone dose required to produce the maximal increase in strength to be between 0.3

*Weight at the first visit was compared with weight at the last visit. The weight gain in the prednisone-treated patients was significant (placebo vs both prednisone groups, $P = .0002$; placebo vs prednisone 0.3 mg/kg, $P = .01$; placebo vs prednisone 0.75 mg/kg $P = .0005$). There was no significant difference in weight gain between the prednisone groups ($P = .18$).

and 0.75 mg/kg. The improvement is rapid and demonstrable within 10 days of starting the drug, becoming maximal by 2 months of treatment.

This study design has a major advantage over the previously reported randomized, double-blind, controlled trial, since the improvement in strength at 10 days occurred prior to the onset of demonstrable side effects, excluding observable differences between treatment and placebo groups as a potentially unblinding factor. Side effects remained absent at the 1-month evaluation. Furthermore, as in the previous double-blind study,[6] there were independent roles for clinical evaluators involved in assessment of strength and function, and principal investigators, who assessed side effects.

We have considered the mechanism of prednisone-induced improvement in our patients. The possibility that the response is a placebo effect is discounted by the use of a randomized, double-blind, placebo-controlled trial in both the present and previous[6] studies. In addition, the response observed represented a rapid and sustained improvement when compared with the natural history, which we have charted in over 200 patients with Duchenne dystrophy.[7,9] Moreover, four negative double-blind, randomized, controlled trials of other medications have provided us with ample data on placebo effects in Duchenne dystrophy.[15-18]

The possibility that prednisone pro-

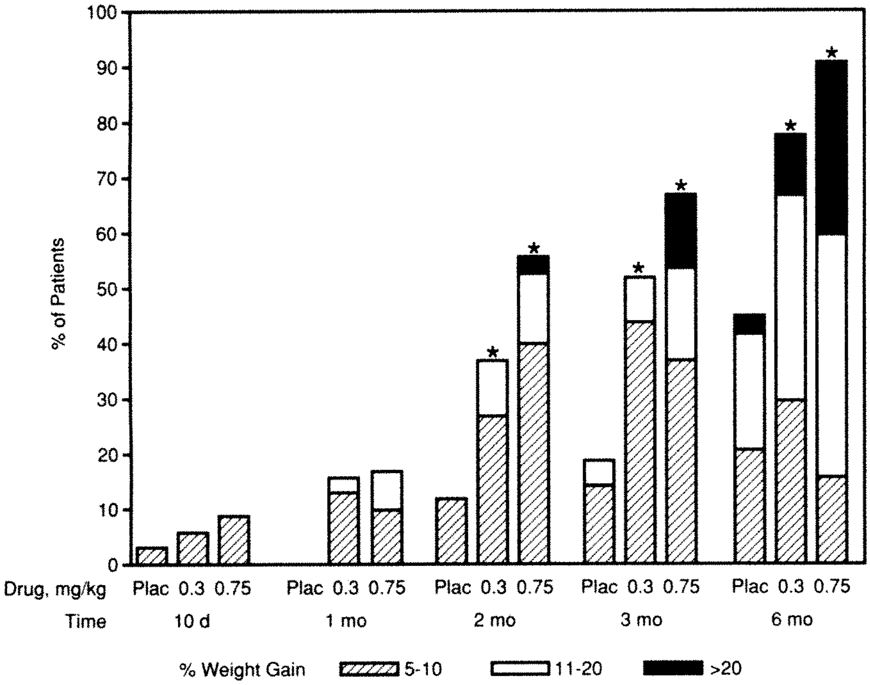

Fig 2.—Percent weight gain of patients with Duchenne dystrophy treated with placebo (Plac) and prednisone, 0.3 mg/kg per day or 0.75 mg/kg per day, at each visit. Values significantly ($P<.05$) different from those in the placebo group are indicated with an asterisk.

duced its benefit by a psychological effect in terms of an increase in motivation was considered. However, the observation of an increase in muscle mass as demonstrated by creatinine excretion in our previous trial[6] provided confirmatory evidence of an actual change in the pathological process within muscle in treated patients. In companion studies conducted in conjunction with our initial treatment trials for prednisone in Duchenne dystrophy, we showed that total body potassium increased to an extent similar to creatinine excretion.[7] Total body potassium provides an independent assessment of lean body mass[19] and confirmed that the increase in creatinine excretion reflects an increase in muscle mass.

Additional studies conducted concurrently with our earlier randomized trial of prednisone[6] have begun to define the basis for the increase in muscle mass, which accompanies the improvement in strength. Measurements of 24-hour urinary excretion of 3-methylhistidine were made before and after 6 months in 103 patients with Duchenne dystrophy.[20] The rate of 3-methylhistidine excretion was adjusted for muscle mass. Six months of prednisone treatment produced a significant decline in 3-methylhistidine excretion (16%), compared with the 3% increase observed in untreated patients.[20] Since 3-methylhistidine is an indirect measure of the rate of muscle breakdown,[21] it appears that muscle mass increases, at least in part, because of a decrease in the rate of muscle breakdown.

Studies carried out at one of the five centers (The Ohio State University) in a subgroup of patients with Duchenne dystrophy addressed the question of the immunosuppressant actions of prednisone in mediation of improved strength and decreased in muscle destruction. Mononuclear cell analyses of muscle biopsy specimens conducted at the conclusion of the prednisone trial demonstrated a marked decrease in the total number of T cells (CD2+) and selectively on the subset of CD8+ cytotoxic/suppressor T cells.[22] Prednisone treatment did not alter the number of necrotic fibers or decrease the infiltration of CD4+, natural killer cells, or macrophages, or the number of B cells.[22] Prednisone treatment had no effect on dystrophin expression following treatment.[23] Thus, it appears that prednisone produces an increase in strength and muscle mass by decreasing the rate of muscle breakdown. However, since the number of necrotic fibers is not decreased, it is possible that the prednisone-induced decrease in cytotoxic lymphocytes allows damaged fibers to undergo regeneration averting muscle breakdown and fiber loss, as reflected by the decrease in 3-methylhistidine excretion. Studies by others in Duchenne dystrophy have shown that the complement cascade is activated in necrotic fibers[24] and that cytotoxic T cells focally invade muscle fibers.[25]

The observations that prednisone improves strength and function in Duchenne dystrophy in this and previous studies,[7,8] as well as reducing inflammatory infiltrates, decreasing 3-methylhistidine urinary excretion, and increasing muscle mass, are not inconsequential in a disease of relentless progression without treatment. Although clinical trials of myoblast transfer in boys with Duchenne dystrophy[26] have begun in hopes of producing dystrophin expression as seen in the mdx mouse model for the disease,[2,3] the widespread applicability of such treatment is unknown.[4] For this reason, we believe that additional studies of the mechanism of prednisone effect on rates of muscle protein synthesis and regulation of hormonal milieu are important. We are also examining the effect of azathioprine in combination with prednisone for a potential steroid-sparing or potentiating effect.[27] Controlled studies of patients with more advanced Duchenne dystrophy and with Becker's dystrophy are in progress. It is also possible that other schedules of prednisone administration (such as pulsed dosage) may be effective and have fewer side effects.

For the present, our studies have defined a dose response to prednisone with maximal benefit achieved at 0.75 mg/kg per day, not equaled by 0.3 mg/kg per day. We recommend that a prednisone dosage of 0.75 mg/kg per day be considered for patients with Duchenne dystrophy who experience functional decline. Our natural history data suggest that patients are most likely to begin such functional decline at age 7.5 years[28] (falling more frequently, more trouble with stair climbing), requiring use of long leg braces between 9 and 10 years. Studies in progress also indicate that long-term prednisone continues to maintain strength and function compared with natural history rates of decline.[29] Side effects such as weight gain, hypertension, or behavioral disturbances may necessitate the reduction or cessation of treatment in some patients.[6,29]

This study was supported, in part, by a grant from the Muscular Dystrophy Association and the following grants from the National Institutes of Health: MO1-RR00034 (Columbus, Ohio), RR0004 and NS22099 (Rochester, NY), RR0036 (St Louis, Mo), and RR00095 (Nashville, Tenn).

The Clinical Investigation of Duchenne Dystrophy Group includes: Shree Pandya, MS (University of Rochester [NY]; Wendy King, LPT, and Linda Signore, RN, MS (Ohio State University College of Medicine, Columbus); Jenny Robison, PT (Vanderbilt University, Nashville, Tenn); Jack Baty, Julaine Florence, MS, Jeanine Schierbecker, PT, and Brad Wilson, MBA (Washington University Medical, St Louis, Mo); and Nancy Matheson-Burden, PT (Walter C. McKenzie Center for Health Sciences, Edmonton, Alberta).

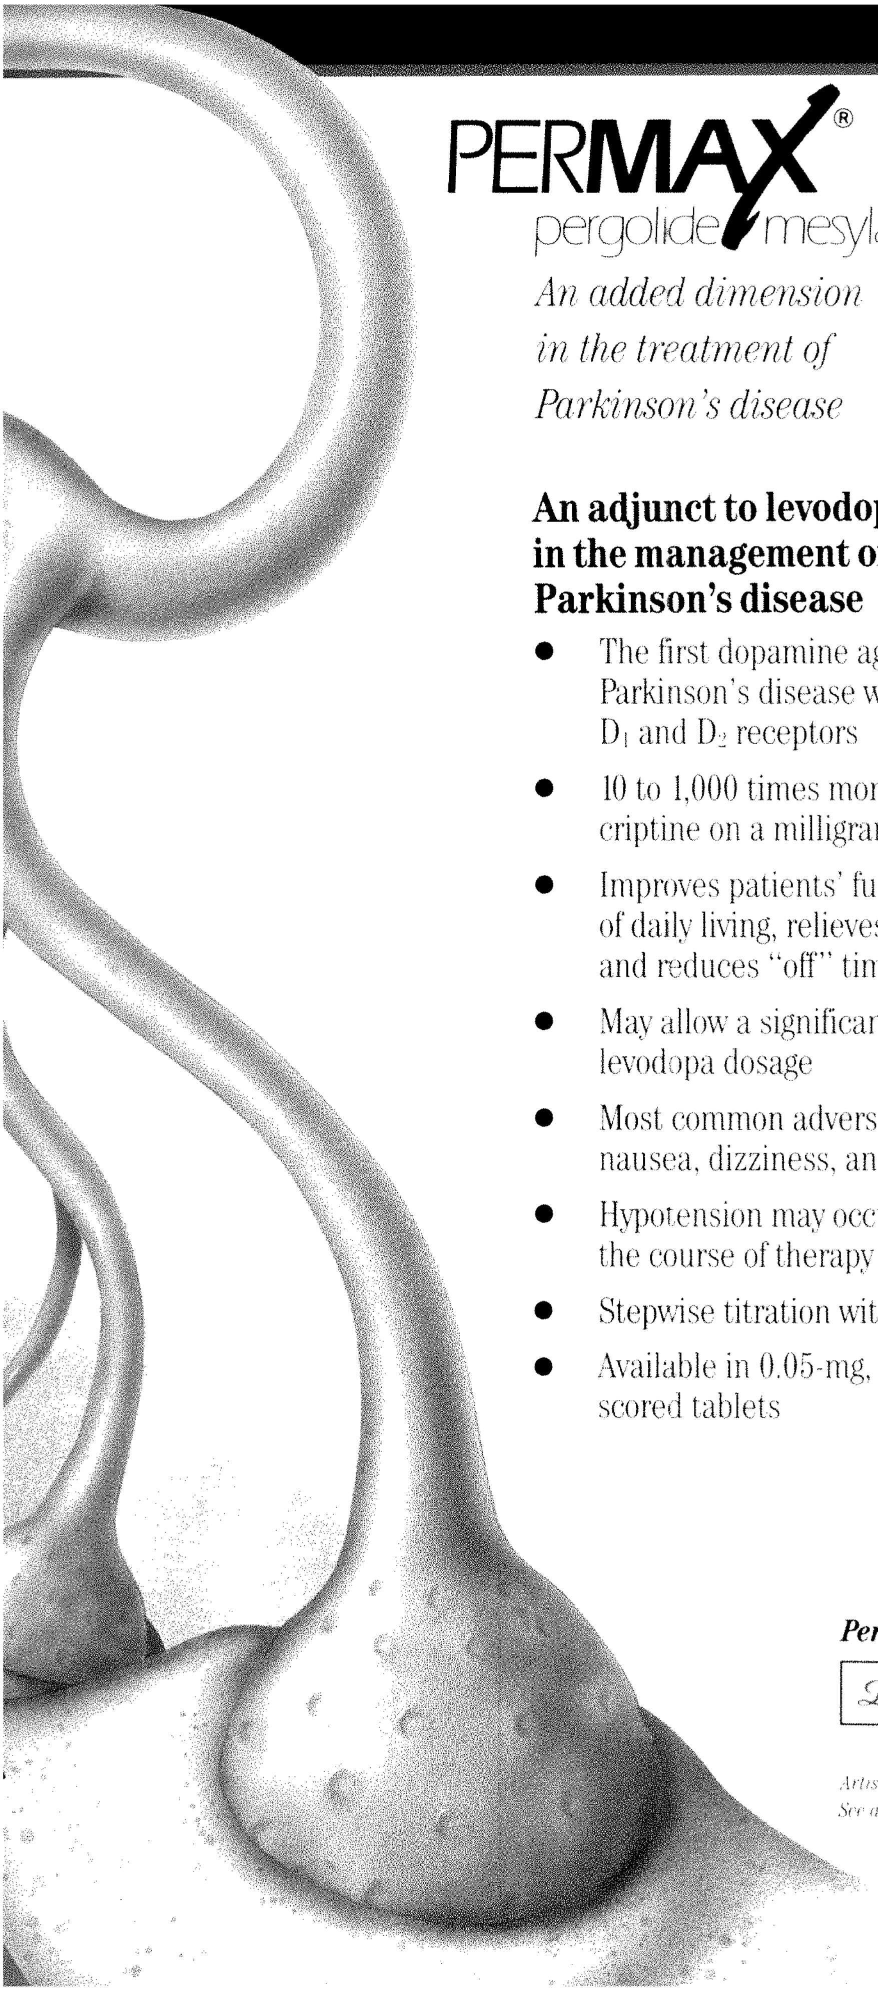
④ Presynaptic neuron
⑤ Postsynaptic neuron
⑥ **Synapse** (synaptic cleft)
⑦ **Uptake** pump
⑧ D_1 receptor
⑨ D_2 receptor



PERMAX®
pergolide mesylate

An added dimension
in the treatment of
Parkinson's disease

An adjunct to levodopa/carbidopa in the management of patients with Parkinson's disease

- The first dopamine agonist indicated for Parkinson's disease with activity at both D_1 and D_2 receptors
- 10 to 1,000 times more potent than bromocriptine on a milligram-per-milligram basis
- Improves patients' functioning in activities of daily living, relieves signs and symptoms, and reduces "off" time
- May allow a significant reduction in levodopa dosage
- Most common adverse events were dyskinesia, nausea, dizziness, and hallucinations
- Hypotension may occur, especially early in the course of therapy
- Stepwise titration without regard to meals
- Available in 0.05-mg, 0.25-mg, and 1-mg scored tablets

See adjacent page for prescribing information.

Permax*

pergolide mesylate

Brief Summary. Consult the package insert for complete prescribing information.

Indications and Usage: Permax is indicated as adjunctive treatment to levodopa/carbidopa in the management of the signs and symptoms of Parkinson's disease.

Evidence to support the efficacy of pergolide mesylate as an antiparkinsonian adjunct was obtained in a multicenter study enrolling 376 patients with mild to moderate Parkinson's disease who were intolerant to levodopa/carbidopa as manifested by moderate to severe dyskinesia and/or on-off phenomena. On average, the sample of patients evaluated had been on levodopa/carbidopa for 3.9 years (range, two days to 16.8 years). The administration of pergolide mesylate permitted a 5% to 30% reduction in the daily dose of levodopa. On average, these patients treated with pergolide mesylate maintained an equivalent or better clinical status than they exhibited at baseline.

Contraindications: Pergolide mesylate is contraindicated in patients who are hypersensitive to this drug or other ergot derivatives.

Warnings: *Symptomatic Hypotension* —In clinical trials, approximately 10% of patients taking pergolide mesylate with levodopa vs 7% taking placebo with levodopa experienced symptomatic orthostatic and/or sustained hypotension, especially during initial treatment. With gradual dosage titration, tolerance to the hypotension usually develops. It is, therefore, important to warn patients of the risk, to begin therapy with low doses, and to increase the dosage in carefully adjusted increments over a period of three to four weeks.

Hallucinosis —In controlled trials, pergolide mesylate with levodopa caused hallucinosis in about 14% of patients as opposed to 3% taking placebo with levodopa. This was of sufficient severity to cause discontinuation of treatment in about 3% of those enrolled; tolerance to this untoward effect was not observed.

Fatalities —In the placebo-controlled trial, two of 187 patients treated with placebo died as compared with one of 189 patients treated with pergolide mesylate. Of the 2,299 patients treated with pergolide mesylate in premarketing studies evaluated as of October 1988, 143 died while on the drug or shortly after discontinuing the drug. The patient population under evaluation was elderly, ill, and at high risk for death. It seems unlikely that pergolide mesylate played any role in these deaths, but the possibility that pergolide shortens survival of patients cannot be excluded with absolute certainty.

In particular, a case-by-case review of the clinical course of the patients who died failed to disclose any unique set of signs, symptoms, or laboratory results that would suggest that treatment with pergolide caused their deaths. Sixty-eight percent (68%) of the patients who died were 65 years of age or over. No death (other than a suicide) occurred within the first month of treatment; most of the patients who died had been on pergolide for years. A relative frequency of the causes of death by organ system are: pulmonary failure/pneumonia, 35%; cardiovascular, 30%; cancer, 11%; unknown, 8.4%; infection, 3.5%; extrapyramidal syndrome, 3.5%; stroke, 2.1%; dysphagia, 2.1%; injury, 1.4%; suicide, 1.4%; dehydration, 0.7%; glomerulonephritis, 0.7%.

Precautions: *General* —Caution should be exercised when administering pergolide mesylate to patients prone to cardiac dysrhythmias.

In a study comparing pergolide mesylate and placebo, patients taking pergolide mesylate were found to have significantly more episodes of atrial premature contractions (APCs) and sinus tachycardia.

The use of pergolide mesylate in patients on levodopa may cause and/or exacerbate preexisting states of confusion and hallucinations (*see* Warnings). Also, the abrupt discontinuation of pergolide mesylate in patients receiving it chronically as an adjunct to levodopa may precipitate the onset of hallucinations and confusion; these may occur within a span of several days. Discontinuation of pergolide should be undertaken gradually whenever possible, even if the patient is to remain on levodopa.

The administration of pergolide mesylate to patients receiving levodopa may cause and/or exacerbate preexisting dyskinesia.

Information for Patients —Patients and their families should be informed of the common adverse consequences of the use of pergolide mesylate (*see* Adverse Reactions) and the risk of hypotension (*see* Warnings).

Patients should be advised to notify their physician if they become pregnant or intend to become pregnant during therapy.

Patients should be advised to notify their physician if they are breast feeding an infant.

Laboratory Tests —No specific laboratory tests are deemed essential for the management of patients on Permax. Periodic routine evaluation of all patients, however, is appropriate.

Drug Interactions —Dopamine antagonists, such as the neuroleptics (phenothiazines, butyrophenones, thioxanthines) or metoclopramide, ordinarily should not be administered concurrently with Permax (a dopamine agonist); these agents may diminish the effectiveness of Permax.

Because pergolide mesylate is approximately 90% associated with plasma proteins, caution should be exercised if pergolide mesylate is coadministered with other drugs known to affect protein binding.

Carcinogenesis, Mutagenesis, and Impairment of Fertility —A two-year carcinogenicity study was conducted in mice using dietary levels of pergolide mesylate equivalent to oral doses of 0.6, 3.7, and 36.4 mg/kg/day in males and 0.6, 4.4, and 40.8 mg/kg/day in females. A two-year study in rats was conducted using dietary levels equivalent to oral doses of 0.04, 0.18, and 0.88 mg/kg/day in males and 0.05, 0.28, and 1.42 mg/kg/day in females. The highest doses tested in the mice and rats were approximately 340 and 12 times the maximum human oral dose administered in controlled clinical trials (6 mg/day equivalent to 0.12 mg/kg/day).

A low incidence of uterine neoplasms occurred in both rats and mice. Endometrial adenomas and carcinomas were observed in rats. Endometrial sarcomas were observed in mice. The occurrence of these neoplasms is probably attributable to the high estrogen/progesterone ratio which would occur in rodents as a result of the prolactin-inhibiting action of pergolide mesylate. The endocrine mechanisms believed to be involved in the rodents are not present in humans. However, even though there is no known correlation between uterine malignancies occurring in pergolide-treated rodents and human risk, there are no human data to substantiate this conclusion.

Pergolide mesylate was evaluated for mutagenic potential in a battery of tests that included an Ames bacterial mutation assay, a DNA repair assay in cultured rat hepatocytes, a point-mutation assay in cultured L5178Y cells, and a determination of chromosome alteration in bone marrow cells of Chinese hamsters. A weak mutagenic response was noted in the in vitro mammalian cell-point-mutation assay using L5178Y cells only after metabolic activation with rat liver microsomes. No mutagenic effects were obtained in the two other in vitro assays and in the in vivo assay. The relevance of these findings to humans is unknown.

A fertility study in male and female mice showed that fertility was maintained at 0.6 and 1.7 mg/kg/day but decreased at 5.6 mg/kg/day. Prolactin has been reported to be involved in stimulating and maintaining progesterone levels required for implantation in mice and, therefore, the impaired fertility at high dose may occur because of depressed prolactin levels.

Usage in Pregnancy—Pregnancy Category B —Reproduction studies were conducted in mice at doses of 5, 16, and 45 mg/kg/day and in rabbits at doses of 2, 6, and 16 mg/kg/day. The highest doses tested in mice and rabbits were 375 and 133 times the 6 mg/day maximum human dose administered in controlled clinical trials. In these studies, there was no evidence of harm to the fetus due to pergolide mesylate.

PR-9002-2 T-149308 © 1991, ELI LILLY AND COMPANY

There are, however, no adequate and well-controlled studies in pregnant women. Among women who received pergolide mesylate for endocrine disorders in premarketing studies, there were 33 pregnancies that resulted in healthy babies and four pregnancies that resulted in congenital abnormalities (two major, two minor); a causal relationship has not been established. Because human data are limited and because animal reproduction studies are not always predictive of human response, this drug should be used during pregnancy only if clearly needed.

Nursing Mothers —It is not known whether this drug is excreted in human milk. The pharmacologic action of pergolide mesylate suggests that it may interfere with lactation. Because many drugs are excreted in human milk and because of the potential for serious adverse reactions to pergolide mesylate in nursing infants, a decision should be made whether to discontinue nursing or to discontinue the drug, taking into account the importance of the drug to the mother.

Pediatric Use —Safety and effectiveness in children have not been established.

Adverse Reactions: *Commonly Observed* —In premarketing clinical trials, the most commonly observed adverse events associated with use of pergolide mesylate which were not seen at an equivalent incidence among placebo-treated patients were: nervous system complaints, including dyskinesia, hallucinations, somnolence, insomnia; digestive complaints, including nausea, constipation, diarrhea, dyspepsia, and respiratory system complaints, including rhinitis.

Associated With Discontinuation of Treatment —Twenty-seven percent (27%) of approximately 1,200 patients receiving pergolide mesylate for treatment of Parkinson's disease in premarketing clinical trials in the US and Canada discontinued treatment due to adverse events. The events most commonly causing discontinuation were related to the nervous system (15.5%), primarily hallucinations (7.8%) and confusion (1.8%).

Fatalities —*See* Warnings.

Incidence in Controlled Clinical Trials —The table that follows enumerates adverse events that occurred at a frequency of 1% or more among patients taking pergolide mesylate who participated in the premarketing controlled clinical trials comparing pergolide mesylate with placebo. In a double-blind, controlled study of six months' duration, patients with Parkinson's disease were continued on levodopa/carbidopa and were randomly assigned to receive either pergolide mesylate or placebo as additional therapy.

The prescriber should be aware that these figures cannot be used to predict the incidence of side effects in the course of usual medical practice where patient characteristics and other factors differ from those which prevailed in the clinical trials. Similarly, the cited frequencies cannot be compared with figures obtained from other clinical investigations involving different treatments, uses, and investigators. The cited figures, however, do provide the prescribing physician with some basis for estimating the relative contribution of drug and nondrug factors to the side-effect incidence rate in the population studied.

Incidence of Treatment-Emergent Adverse Experiences in the Placebo-Controlled Clinical Trial

*Events reported by at least 1% of patients receiving pergolide mesylate are included.

Events Observed During the Premarketing Evaluation of Permax —This section reports event frequencies evaluated as of October 1988 for adverse events ocurring in a group of approximately 1,800 patients who took multiple doses of pergolide mesylate. The conditions and duration of exposure to pergolide mesylate varied greatly, involving well-controlled studies as well as experience in open and uncontrolled clinical settings. In the absence of appropriate controls in some of the studies, a causal relationship between these events and treatment with pergolide mesylate cannot be determined.

The following enumeration by organ system describes events in terms of their relative frequency of reporting in the data base. Events of major clinical importance are also described in the Warnings and Precautions sections.

The following definitions of frequency are used: frequent adverse events are defined as those occurring in at least 1/100 patients; infrequent adverse events are those occurring in 1/100 to 1/1,000 patients; rare events are those occurring in fewer than 1/1,000 patients.

Body as a Whole —*Frequent:* headache, asthenia, accidental injury, abdominal pain, chest pain, back pain, flu syndrome, neck pain, fever; *Infrequent:* facial edema, chills, enlarged abdomen, malaise, neoplasm, hernia, pelvic pain, sepsis, cellulitis, moniliasis, abscess, jaw pain, hypothermia; *Rare:* acute abdominal syndrome, LE syndrome.

Cardiovascular System —*Frequent:* postural hypotension, syncope, hypertension, palpitations, vasodilatations, congestive heart failure; *Infrequent:* myocardial infarction, tachycardia, heart arrest, abnormal electrocardiogram, angina pectoris, thrombophlebitis, bradycardia, ventricular extrasystoles, cerebrovascular accident, ventricular tachycardia, cerebral ischemia, atrial fibrillation, varicose vein, pulmonary embolus, AV block, shock; *Rare:* vasculitis, pulmonary hypertension, pericarditis, migraine, heart block, cerebral hemorrhage.

Digestive System —*Frequent:* nausea, vomiting, dyspepsia, diarrhea, constipation, dry mouth, dysphagia; *Infrequent:* flatulence, abnormal liver function tests, increased appetite, salivary gland enlargement, thirst, gastroenteritis, gastritis, periodontal abscess, intestinal obstruction, nausea and vomiting, gingivitis, esophagitis, cholelithiasis, tooth caries, hepatitis, stomach ulcer, melena, hepatomegaly, hematemesis, eructation; *Rare:* sialadenitis, peptic ulcer, pancreatitis, jaundice, glossitis, fecal incontinence, duodenitis, colitis, cholecystitis, aphthous stomatitis, esophageal ulcer.

Endocrine System —*Infrequent:* hypothyroidism, adenoma, diabetes mellitus, ADH inappropriate; *Rare:* endocrine disorder, thyroid adenoma.

Hemic and Lymphatic System —*Frequent:* anemia; *Infrequent:* leukopenia, lymphadenopathy, leukocytosis, thrombocytopenia, petechia, megaloblastic anemia, cyanosis; *Rare:* purpura, lymphocytosis, eosinophilia, thrombocythemia, acute lymphoblastic leukemia, polycythemia, splenomegaly.

Metabolic and Nutritional System —*Frequent:* peripheral edema, weight loss, weight gain; *Infrequent:* dehydration, hypokalemia, hypoglycemia, iron deficiency anemia, hyperglycemia, gout, hypercholesteremia; *Rare:* electrolyte imbalance, cachexia, acidosis, hyperuricemia.

Musculoskeletal System —*Frequent:* twitching, myalgia, arthralgia; *Infrequent:* bone pain, tenosynovitis, myositis, bone sarcoma, arthritis; *Rare:* osteoporosis, muscle atrophy, osteomyelitis.

Nervous System —*Frequent:* dyskinesia, dizziness, hallucinations, confusion, somnolence, insomnia, dystonia, paresthesia, depression, anxiety, tremor, akinesia, extrapyramidal syndrome, abnormal gait, abnormal dreams, incoordination, psychosis, personality disorder, nervousness, choreoathetosis, amnesia, paranoid reaction, abnormal thinking; *Infrequent:* akathisia, neuropathy, neuralgia, hypertonia, delusion, convulsion, libido increased, euphoria, emotional lability, libido decreased, vertigo, myoclonus, coma, apathy, paralysis, neurosis, hyperkinesia, ataxia, acute brain syndrome, torticollis, meningitis, manic reaction, hypokinesia, hostility, agitation, hypotonia; *Rare:* stupor, neuritis, intracranial hypertension, hemiplegia, facial paralysis, brain edema, myelitis, hallucinations and confusion after abrupt discontinuation.

Respiratory System —*Frequent:* rhinitis, dyspnea, pneumonia, pharyngitis, cough increased; *Infrequent:* epistaxis, hiccup, sinusitis, bronchitis, voice alteration, hemoptysis, asthma, lung edema, pleural effusion, laryngitis, emphysema, apnea, hyperventilation; *Rare:* pneumothorax, lung fibrosis, larynx edema, hypoxia, hypoventilation, hemothorax, carcinoma of lung.

Skin and Appendages System —*Frequent:* sweating, rash; *Infrequent:* skin discoloration, pruritus, acne, skin ulcer, alopecia, dry skin, skin carcinoma, seborrhea, hirsutism, herpes simplex, eczema, fungal dermatitis, herpes zoster; *Rare:* vesiculobullous rash, subcutaneous nodule, skin nodule, skin benign neoplasm, lichenoid dermatitis.

Special Senses System —*Frequent:* diplopia; *Infrequent:* otitis media, conjunctivitis, tinnitus, deafness, taste perversion, ear pain, eye pain, glaucoma, eye hemorrhage, photophobia, visual field defect; *Rare:* blindness, cataract, retinal detachment, retinal vascular disorder.

Urogenital System —*Frequent:* urinary tract infection, urinary frequency, urinary incontinence, hematuria, dysmenorrhea; *Infrequent:* dysuria, breast pain, menorrhagia, impotence, cystitis, urinary retention, abortion, vaginal hemorrhage, vaginitis, priapism, kidney calculus, fibrocystic breast, lactation, uterine hemorrhage, urolithiasis, salpingitis, pyuria, metrorrhagia, menopause, kidney failure, breast carcinoma, cervical carcinoma; *Rare:* amenorrhea, bladder carcinoma, breast engorgement, epididymitis, hypogonadism, leukorrhea, nephrosis, pyelonephritis, urethral pain, uricaciduria, withdrawal bleeding.

Positron Emission Tomography in Progressive Supranuclear Palsy

Mohit H. Bhatt, MD; Barry J. Snow, MBChB, FRACP; W. R. Wayne Martin, MD, FRCPC;
Richard Peppard, MBBS, FRACP; Donald B. Calne, DM, FRCP, FRCPC

• Positron emission tomography with 6-[^{18}F]fluoro-L-dopa (6-FD) provides in vivo information on the function of nigrostriatal dopaminergic neurons. We used 6-FD and positron emission tomography to investigate the integrity of the nigrostriatal system in seven patients with progressive supranuclear palsy. All patients had axial hypertonia, vertical gaze palsy, and parkinsonian features. Dementia, pyramidal signs, and ataxia were seen in varying proportions. We analyzed the scans with a graphic method to calculate a steady-state 6-FD uptake rate constant for the whole striatum. Results were compared with those obtained in seven age-matched controls. As a group, the patients with progressive supranuclear palsy had reduced 6-FD uptake constants. The 6-FD uptake constant correlated inversely with the duration of the disease. Normal positron emission tographic findings in one patient with the shortest duration of symptoms suggests that in early progressive supranuclear palsy, parkinsonism may relate to dysfunction distal to the dopaminergic neurons.

(*Arch Neurol.* 1991;48:389-391)

Progressive supranuclear palsy (PSP) is characterized by supranuclear ophthalmoplegia, parkinsonism, pseudobulbar palsy, axial hypertonia, and dementia with variable cerebellar ataxia and pyramidal dysfunction.[1-3] The parkinsonism in PSP may be related, at least in part, to dysfunction of the dopaminergic pathway. In vivo studies with positron emission tomography (PET) should add to our understanding of the pathophysiologic processes involved in disorders in which the dopaminergic pathways may be preferentially affected, such as PSP. Positron emission tomography is particularly suited for the evaluation of early disease, in which postmortem information is seldom available.

With 6-[^{18}F]fluoro-L-dopa (6-FD) and PET, we can study the integrity of nigrostriatal dopaminergic function. The injected 6-FD is transferred from blood to the striatum, where it is converted to fluorodopamine by dopa-decarboxylase and trapped in the presynaptic vesicles. The retention of radioactivity within the striatum is related to the functional integrity of the presynaptic nigrostriatal dopaminergic nerve endings. This can be quantified by calculating a 6-FD uptake rate constant.[4] In idiopathic parkinsonism, the accumulation of 6-FD and its metabolites in the striatum is decreased, implying impairment in the presynaptic nigrostriatal dopaminergic function.[5-7]

The aim of this study was to utilize PET to evaluate presynaptic nigrostriatal dopaminergic function in PSP.

The diagnosis of PSP was independently confirmed by two neurologists, using the clinical criteria of Maher and Lees.[8] The disease duration was estimated from history furnished by the patients and other family members and from the medical records.

There were three men and four women with PSP; their ages ranged from 60 to 73 years (mean, 66.4 years). The average duration of symptoms from onset to PET scan was 42.5 months (range, 16 to 72 months).

REPORT OF CASES

CASE 1.—A 67-year-old woman presented with a 36-month history of progressive memory loss, falls, and difficulty in using her hands. Since onset, her mobility, memory, reasoning, and language had deteriorated, and she had developed urinary incontinence 1 year prior to her PET scan. On examination, there was marked perseveration of speech and motor tasks. She had loss of recent memory. Conjugate eye movements were absent in downward and left gaze and impaired in up gaze but complete by vestibulo-ocular maneuver. She had hypomimia, brisk facial reflexes, axial hypertonia, cogwheel rigidity at the wrists, and brisk deep tendon reflexes. The plantar responses were flexor. Computed tomography (CT) of the patient's head showed generalized brain-stem and cortical atrophy.

CASE 2.—A 59-year-old man presented with a 49-month history of progressive imbalance and diplopia. He had a history of impairment in recent memory, dysphagia, and hypophonia. On examination, he had mild recent memory loss. His eye movements were impaired in down gaze by 50%, and up gaze was only possible to the midline. The limitation in gaze could not be overcome by the vestibulo-ocular maneuver. The blink rate was markedly reduced, and the facial reflexes were brisk. He had poor balance and walked with a broad-based gait, with his neck held in retroflexion. The tendon reflexes were brisk. The plantar responses were flexor. Magnetic resonance imaging showed temporoparietal and generalized brain-stem atrophy.

CASE 3.—A 61-year-old man presented with a 37-month history of progressively deteriorating balance, frequent falls, loss of re-

cent memory, and change in personality. He had difficulty in focusing his vision. On examination, his speech was dysarthric and his recent memory was impaired. He had a 75% limitation in upward and downward gaze and a 25% limitation in horizontal gaze. Saccades were absent vertically and impaired horizontally. Vestibulo-ocular responses were complete in both eyes. The patient's blink rate was less than one per minute, and he had hypomimia. His axial tone was normal. All his tendon reflexes were brisk. The plantar responses were flexor, and there was minimal hand ataxia. Magnetic resonance imaging showed predominant brain-stem atrophy.

Case 4.—A 62-year-old woman presented with a 16-month history of frequent falls. On examination, there was no evidence of dementia. Her vertical conjugate eye movements were absent and horizontal movements impaired, with gaze-evoked horizontal nystagmus. She had mild cogwheel rigidity at her wrists and increased axial tone. Her gait was wide based and she could not walk tandem. Her reflexes were normal. Magnetic resonance imaging showed prominent temporal atrophy, with midbrain and pontine atrophy. At the time of her PET scan, she was least affected and was symptomatic for the shortest duration compared with other patients. Two years after the PET scan, her illness had progressed with the development of marked parkinsonian features, dysarthria, and dysphagia without dementia. She declined a second PET scan.

Case 5.—A 69-year-old woman presented with a 72-month history of frequent falls, dysarthria, and diplopia. On examination, she had impaired recent memory and acalculia. Her upward and downward gaze were impaired, and there was abduction nystagmus in both eyes. Conjugate eye movements were slow in all directions, especially downward. Vestibulo-ocular response was improved only in the upward direction. The blink rate was one per minute. She had hypomimia and brisk facial reflexes with an increased jaw jerk. Her axial tone was increased. Cogwheel rigidity was present in all limbs, and she had marked bradykinesia. The tendon reflexes were normal, and the plantar responses were flexor. Magnetic resonance imaging showed generalized cortical and midbrain atrophy.

Case 6.—A 73-year-old woman presented with a 40-month history of frequent falls, diplopia, and hand tremor. On examination, there was no evidence of dementia. Her vertical gaze was restricted, but her horizontal eye movements were full. Her saccadic eye movements were slow, and she had to use excessive neck movements to look to either side. Her vestibulo-ocular response improved the range of her vertical eye movements. Cogwheel rigidity was present at the wrists, and the axial tone was increased. She had a resting hand tremor with ataxia of the left arm and an ataxic gait. The tendon reflexes were exaggerated with equivocal plantar responses. Magnetic resonance imaging showed generalized cortical and brain-stem atrophy.

Case 7.—A 72-year-old man presented with a 48-month history of a slow shuffling gait and frequent falls. Subsequently, he developed profound memory loss, dysphasic speech, urinary incontinence, and lack of spontaneity. On examination, he had profound dementia. Vertical gaze was restricted, pursuit was broken, and saccadic eye movements were slow. The vestibulo-ocular response was normal. The blink rate was two per minute. Axial tone was increased, and cogwheel rigidity was present at both wrists. Tendon reflexes were exaggerated with extensor plantar responses. Magnetic resonance imaging showed generalized cortical and brain-stem atrophy.

Patients 2, 3, 5, 6,and 7 were taking levodopa-carbidopa (Sinemet); patients 3 and 5 were also taking bromocriptine. Patients 1 and 4 had stopped all treatment because of poor response. There was no clinical improvement noted among the patients who were taking medication. None of the patients were taking neuroleptics prior to their PET scan.

Seven age-matched controls underwent PET scans. The controls were neurologically normal and not taking any medication. The ages of the controls ranged from 57 to 73 years (mean, 65.5 years). The individual ages of the controls and patients differed by a maximum of 3 years.

METHODS

We used a PET protocol that has been approved by the University of British Columbia, Vancouver, Canada. All medications were withdrawn the night before the scan. Positron-emitting fluorine 18 was incorporated into a dopa derivative to produce 6-FD using a cyclotron (TRIUMF CP-42), as described elsewhere.[9,10] The PET studies were performed with the University of British Columbia TRIUMF PETT VI system.[11] This apparatus permits emission data to be collected simultaneously from seven contiguous axial slices, with a center-to-center slice separation of 14 mm, an average axial resolution of approximately 11-mm full width at half maximum, and an in-plane resolution averaging 9.2-mm full width at half maximum. All patients underwent a magnetic resonance imaging scan scan (Picker 0.15-T magnet), except for patient 1 who underwent a CT scan. Magnetic resonance imaging or CT was performed to locate the plane of the striatum. This plane was identified and marked above the orbitomeatal line with a pair of laser beams. The patient was then positioned so that the magnetic resonance imaging or CT plane that best visualized the striatum corresponded to the fifth PET slice.

One hour before the scan, 100 mg of carbidopa was administered orally. This dose of carbidopa prevents peripheral decarboxylation of labeled dopa.[12] During scanning, the patient lay supine with head movements limited by a molded thermoplastic face mask. A transmission scan was performed prior to tracer administration to permit attenuation correction to be applied to the emission data. Each subject received 74 to 129.5 MBq of 6-FD. Twelve sequential emission scans, each lasting 10 minutes, were performed, starting immediately after tracer administration.

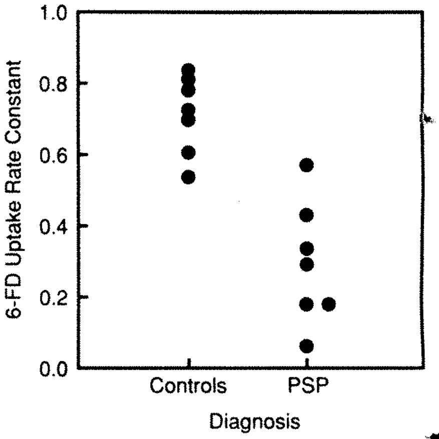

Fig 1.—The individual 6-[^{18}F]fluoro-L-dopa (6-FD) uptake rate constants of the patients with progressive supranuclear palsy (PSP) and the controls are compared. As a group, patients with PSP had significantly reduced uptake rate constants compared with age-matched controls (PSP group mean[SD], 0.29[0.181]; controls, 0.71[0.099]; $P<.001$).

Sequential blood samples were obtained in each subject via an indwelling radial artery catheter, and the total plasma radioactivity was measured in each sample. The relationship between plasma 6-FD radioactivity and radioactive metabolites vs time was calculated.[13] Striatal regions of interest with an area of 12 cm^2 were placed on all slices in which striatal radioactivity was evident in excess of the background. Two cortical regions of interest occupying an area of 9 cm^2 were placed in the posterior temporoparietal cortex. Tissue and plasma measurement were analyzed by a graphic method as described previously.[4]

To minimize the partial volume effect due to striatal atrophy, we used large regions of interest to sample the whole striatum. Radioactivity in small structures may be underestimated owing to the partial volume effect, as the counts are distributed over a larger area. Despite a wide distribution, however, counts are conserved.[14] Therefore, a large region of interest will measure total radioactivity in the structure of interest.[4]

RESULTS

The 6-FD uptake constant among the PSP group was significantly reduced (PSP group mean[SD], 0.29[0.181]; controls, 0.71[0.099]; $P<.001$, *t* test), compared with that among controls (Fig 1). The uptake constant among the patients with PSP correlated inversely with the duration of symptoms ($r=.85$; $P=.015$) (Fig 2).

The magnetic resonance imaging and CT features of these patients conformed to previously reported criteria for the diagnosis of PSP.[15]

COMMENT

We found significantly reduced 6-FD uptake rate constants in patients with PSP compared with age-matched controls. The reduction correlated with the duration of the disease. Our results im-

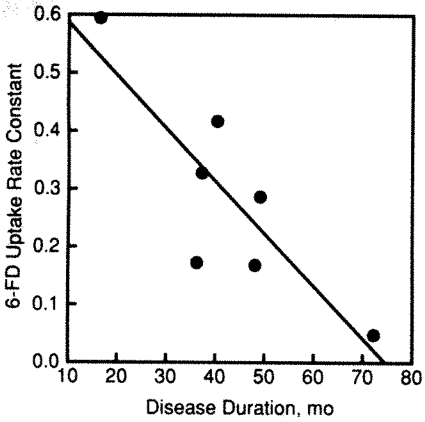

Fig 2.—The 6-[^{18}F]fluoro-L-dopa (6-FD) uptake rate constant for the patients with progressive supranuclear palsy is plotted as a function of disease duration ($r = .85$; $P = .015$).

ply presynaptic nigrostriatal dopaminergic loss and are consistent with those in previous reports.[16] Our findings are in accord with the neuropathologic changes and the severe dopaminergic loss on neurochemical examination of the nigrostriatal pathway in PSP.[1,3,17-19]

Although presynaptic dopaminergic input almost certainly plays an important role in the parkinsonian manifestations in PSP, postsynaptic dopaminergic receptors are also known to be affected in the disease process.[20-22] Baron et al[21] have shown reduced tritiated spiperone binding in early and late cases of PSP. Similarly, a poor therapeutic response in all our patients early in the disease indirectly suggests early involvement of the postsynaptic dopaminergic nigrostriatal system. The parkinsonism in patient 4, who had normal findings on PET and the shortest duration of symptoms, further suggests that there may be postsynaptic dysfunction early in the disease. Alternatively, there could be a defect in dopa synthesis, which would not be detected by PET with 6-FD.

We have found reduced 6-FD uptake rate constants in early idiopathic parkinsonism (unpublished data, 1985). In contrast, the uptake rate constant was normal in our patient with early parkinsonism due to PSP. This suggests that there may be relatively minor presynaptic dopaminergic loss at the time of onset of symptoms in PSP. Since the mean interval from onset of symptoms to diagnosis of PSP is 3.9 years,[8] most patients already have established nigrostriatal dopaminergic loss at the time of diagnosis. In such patients, clinical features may relate to combined presynaptic and postsynaptic dopaminergic dysfunction.

Along with the widespread cholinergic deficit[19] and the reduced frontal lobe glucose utilization,[16,23,24] depressed dopaminergic input to the caudate nucleus has been implicated in the dementia of PSP.[18] Our findings in patients 4 and 6, who had normal mental status and the least affected striatal 6-FD uptake (compared with the rest of the patients), are consistent with the concept that deficient dopaminergic input to the striatum may play a role in the dementia of PSP.[18]

Atypical clinical manifestations in patients with PSP are well recognized.[25] A larger study combining careful clinical evaluation with presynaptic and postsynaptic PET studies of the nigrostriatal pathway would help to elucidate the pathophysiologic processes of PSP.

This study was supported, in part, by the Medical Research Council of Canada, the Dystonia Medical Research Foundation, the Parkinson Foundation of Canada, the American Parkinson Disease Association, and the University Hospital Foundation. Dr Bhatt was partly supported by the Birla Smarak Kosh, Bombay, India.

The authors thank David Li, Department of Radiology, University of British Columbia, Vancouver, Canada, and Sandra Cooper, Poppy Schofield, Thomas Ruth, Michael Adam, Kellie Hewitt, and Salma Jivan, University of British Columbia TRIUMF/PET Program, for their technical help.

Idiopathic Intracranial Hypertension Without Papilledema

John Marcelis, MD, Stephen D. Silberstein, MD

• We describe 10 patients with idiopathic intracranial hypertension who did not have papilledema. Idiopathic intracranial hypertension without papilledema, although rarely reported, may well be a clinically important headache syndrome. Historical and demographic features of patients with idiopathic intracranial hypertension without papilledema are similar to those of patients with papilledema. Obese women with chronic daily headache and symptoms of increased intracranial pressure, pulsatile tinnitus, history of head trauma or meningitis, an empty sella on imaging studies, or a headache that is unrelieved by standard therapy should have a diagnostic lumbar puncture. Findings from laboratory and neurologic investigations are normal in most patients with idiopathic intracranial hypertension without papilledema. Initial management should include removal of possible inciting agents, weight loss if applicable, and standard headache therapy. Lumbar puncture and diuretic therapy should precede a trial of corticosteroids. Surgery (lumboperitoneal or ventriculoperitoneal shunt or perhaps optic nerve sheath fenestration) may be indicated for prolonged incapacitating headache that is not responsive to medical management or lumbar puncture.

(*Arch Neurol.* 1991;48:392-399)

Idiopathic intracranial hypertension (IIH), also known as pseudotumor cerebri or benign intracranial hypertension, is characterized by headache, increased intracranial pressure, and papilledema. In patients with this condition, results of the neurologic examination are normal, except for an occasional sixth nerve palsy. Findings from neuroradiologic investigations are usually normal but may show small ventricles or an empty sella.[1-8] Pseudotumor cerebri was originally described by Quincke[9] in 1897, with bilateral papilledema as the cardinal physical sign. However, in 1972, Lipton and Michelson[10] reported the first case of benign intracranial hypertension without papilledema, and since 1972, several authors have reported IIH with unilateral,[11] asymmetric,[12] or no[13,14] papilledema.

We describe a series of 10 patients with IIH who did not have papilledema.

MATERIALS AND METHODS

All 10 patients were referred for neurologic evaluation of headache between 1977 and 1990. We obtained histories directly from the patient and chart review. We emphasized the character, location, duration, frequency, and associated headache symptoms, and we reviewed possible inciting conditions.[15]

All patients underwent complete general, neurologic, and ophthalmoscopic examinations. We recorded age, sex, weight, blood pressure, ophthalmoscopic findings, visual fields, and evidence of head trauma. Seven patients had endocrinologic consultation for obesity or menstrual irregularities. Laboratory studies included an automated chemistry profile, complete blood cell count with differential cell count, and tests for prothrombin time, partial thromboplastin time, erythrocyte sedimentation rate, antinuclear antibody, rheumatoid factor, and rapid plasma reagin. Endocrinologic laboratory studies on seven patients included determinations of serum prolactin, follicle-stimulating hormone, luteinizing hormone, corticotropin, triiodothyronine (resin uptake) thyroxine, thyrotropin, and cortisol levels. Urine samples for 24-hour free cortisol, 17-hydroxysteroids, 17-ketosteroids, and 17-ketogenic steroids were obtained from five patients.

All patients had a computed tomographic (CT) or magnetic resonance imaging (MRI) scan of the head done, or both; all patients also had single or multiple lumbar punctures (LPs) done. All LPs were performed by the same operator (S.D.S.).

The patient was positioned in the lateral decubitus position on a level surface, with the knees extended and neck and sagittal sinus on the same plane as the spinal canal. A No. 18- or 20-gauge spinal needle was introduced at the L4-5 spinal level; the manometer was positioned at a 90° angle to the spinal canal. The opening pressure was recorded with the use of a standard manometer that was connected to the spinal needle by sterile tubing, with the patient relaxed and breathing easily.

REPORT OF CASES

Tables 1 and 2 give the histories, findings from physical examinations and other investigations, and treatment and follow-up of patients with IIH who did not have papilledema. We report the following three illustrative cases regarding this condition.

CASE 2.—A 40-year-old woman was originally seen in 1989, with a 3-year history of daily headaches. These headaches were continuous, severe, and pounding; worse in the morning; usually localized to the right orbit and temple, but at times bilateral; and associated with nausea, depression, and sleep disturbance. Her medical history revealed irritable bowel syndrome and dysmenorrhea.

On examination, the patient was obese (75 kg, 155 cm) and normotensive. Results of a neurologic examination were normal. Neuro-ophthalmologic examination demonstrated a visual acuity of 20/30 OU and normal visual fields. Ophthalmoscopic examination revealed no papilledema, a benign nevus, and spontaneous venous pulsations. A fluorescein angiogram was normal.

The opening pressure on LP was 330 mm of cerebrospinal fluid (CSF). A CT scan and an MRI scan showed an empty sella with normal-sized, but slightly asymmetric, ventricles. Results of routine laboratory and endocrine studies, including determination of serum prolactin, luteinizing hormone, follicle-stimulating hormone, and urinary 17-hydroxysteroid and 17-ketogenic steroid levels, were normal. The CSF composition, VDRL, and cultures were negative.

Before our evaluation, treatment modalities included intravenous morphine sulfate drip, cyproheptadine hydrochloride, β-adrenergic blockade, calcium channel blockade, tricyclic antidepressants, phenelzine sulfate, lithium carbonate, methylprednisolone acetate, phenytoin sodium, and biofeedback.

At admission to Germantown Hospital, Philadelphia, Pa, the patient was being treated with meperidine hydrochloride, propranolol hydrochloride, lithium carbonate, and clonazepam. She was detoxified from the narcotics. Lithium carbonate, which has been implicated in producing IIH, and β-adrenergic blockers were discontinued.

Sequential treatment with dihydroergotamine mesylate, steroids, and loop diuretics provided minimal relief. An LP relieved the patient's headaches for 4 to 7 hours. In October 1989, she had a ventriculoperitoneal shunt, which brought immediate headache relief. By January 1990, she had only occasional migraine headaches that were relieved with dihydroergotamine, and she returned to work (after being disabled for 2 years).

CASE 3.—In December 1986, a 43-year-old woman with a history of syncope, subarachnoid hemorrhage, cataracts, coronary artery disease, hypertension, and obesity was reexamined for a 1-year history of daily headache.

Accepted for publication October 8, 1990.

From the Department of Internal Medicine, Temple University Hospital (Dr Marcelis), the Comprehensive Headache Center, Germantown Hospital and Medical Center (Dr Silberstein), and the Department of Neurology, Temple University School of Medicine (Dr Silberstein), Philadelphia, Pa.

Reprint requests to Germantown Neurological Associates, 1 Penn Blvd, Philadephia, PA 19144 (Dr Silberstein).

The headache, noted on awakening, was bifrontal, dull, and achy, and it associated with pulsatile tinnitus, dizziness, and sleep disturbance.

The patient was originally admitted to Germantown Hospital in November 1979, with the acute onset of severe occipital headache and neck pain and stiffness. Subarachnoid hemorrhage was diagnosed. The CSF was grossly bloody. A CT scan and cerebral arteriogram were normal. She was treated with intravenous dexamethasone sodium phosphate and antihypertensive medication. Follow-up LPs showed clearing of CSF. Repeated CT scans remained normal. She had no neurologic sequelae, except for daily headache. After discharge, the headaches were controlled with diuretics, β-adrenergic blockers, and tapering doses of steroids. Steroids were discontinued in June 1980. In February 1981, she had visual loss in the right eye from a dense cataract.

In December 1986, examination disclosed a notable finding for obesity (104 kg, 160 cm) and 2/6 systolic flow murmur. Results of neurologic examination were normal. Ophthalmologic examination demonstrated a dense right cataract; visual acuity was 20/20 OS, with light perception in the right eye. Papilledema was absent; spontaneous venous pulsations were present. A fluorescein angiogram was normal.

In December 1986, an LP showed an opening pressure of 270 mm of CSF. The CSF composition, cultures, and VDRL were normal, except for a low protein level (0.13 g/L). Findings from routine and endocrinologic laboratory studies were normal, as were a CT scan and an electroencephalogram.

Sequential use of β-adrenergic blockers, diuretic therapy, methylprednisolone, and serial LPs decreased the severity of headache. In March 1990, the patient's LP showed an opening pressure of 260 mm of CSF. The headache was promptly relieved by LP, but recurred in weeks to months.

Case 10.—A 46-year-old woman was originally seen at Germantown Hospital in May 1986. Headaches, which she had had since the age of 6 years, had gradually increased in severity and frequency during the 3 years before examination. They occurred five to six times each week and lasted 3 to 4 hours. They were pulsating, located in the left orbit and temple, precipitated by sunlight, and associated with nausea. In addition, she had continuous daily headaches, similar in location but less intense, which were present in the morning. Her medical history was significant for hypothyroidism that required daily levothyroxine sodium supplementation (0.2 mg).

At examination, the patient was obese (82.6 kg, 172.7 cm), normotensive (150/84 mm Hg), and clinically euthyroid. Results of a neurologic examination were normal. Ophthalmologic examination revealed a visual acuity of 20/40 OU, normal visual fields, spontaneous venous pulsations, and no papilledema. A fluorescein angiogram was normal. A CT scan and MRI scan of the head and electroencephalogram were normal.

From 1986 through 1989, the patient was treated with oral ergotamine tartrate preparations, calcium channel antagonists, tricyclic antidepressants, monoamine oxidase inhibitors, β-blockers, and nonsteroidal anti-inflammatory agents. She was most recently treated with methylprednisolone, but her headache recurred when the dose was tapered.

An LP was performed in March 1990. The opening pressure was 255 mm of CSF. The CSF composition, cultures, and VDRL were normal. Headache was completely and promptly relieved following LP.

On follow-up, corticosteroids were discontinued, and diuretic therapy was started. The patient usually had headache-free periods that lasted from 2 days to 2 weeks, with a repeated LP yielding immediate relief.

RESULTS

Ten patients with intracranial hypertension without papilledema were examined from 1977 to 1990 (Tables 1 through 3).

Historical and Clinical Features

All patients had chronic daily headache with migrainous features (Table 3). The headache was bilateral in five of 10 patients and pulsating in eight of 10. All 10 patients had severe, daily, continuous headaches; all headaches lasted for greater than 2 weeks. Four patients had pulsatile tinnitus. All patients had headaches on awakening; nine of 10 had nausea or vomiting. Two patients had headaches that worsened on coughing or on Valsalva's maneuver.

The mean duration of symptoms before diagnosis was 76.2 months (range, 3 to 252 months; median, 36 months). Three patients had a history of significant head trauma. One patient had had meningitis, and one patient had had a subarachnoid hemorrhage. Four patients had controlled hypertension. Six of eight women had menstrual irregularities. Two patients were being treated with thyroid hormone replacement for primary hypothyroidism. One woman was taking replacement estrogens (estrogen/progesterone cycled), and one woman was receiving chronic steroid therapy for Still's disease.

The patients ranged in age from 26 to 46 years (mean age, 37.5 years). Eight of the 10 patients were women. Eight patients were obese (>25% above ideal body weight) by Metropolitan Life Insurance Company tables of ideal weight for height.[16] Results of neurologic examinations were normal in all patients (Table 1).

Ocular Examinations

All patients underwent formal ophthalmologic examinations (Table 1). One patient had pseudopapilledema with buried drusen, and one patient had a benign retinal nevus. Findings from visual field studies were normal in all but two patients. One patient had a dense cataract with only light perception in the affected eye, and one patient had a bilateral superior altitudinal field defect. None of the patients had papilledema, exudates, hemorrhages, an enlarged blind spot, elevated intraocular pressure, or abnormal pupillary responses. Spontaneous venous pulsations were present in all but one patient. Fluorescein angiograms were normal in the seven patients who were tested.

Laboratory Findings

Findings from routine laboratory studies were normal for all patients; these studies included tests for antinuclear antibody, rheumatoid factor, erythrocyte sedimentation rate, and rapid plasma reagin. Also, findings from endocrinologic laboratory investigations for obesity or menstrual irregularities were normal in five of seven patients who were studied. Two patients had a slightly elevated serum cortisol level, but it was appropriately suppressed with dexamethasone acetate, and corticotropin levels were normal.

All patients underwent a CT or MRI scan of the head, or both. Seven had completely normal study results. Two patients had an empty sella, and one patient had symmetrically small ventricles. There was no evidence of an intracranial mass or hydrocephalus in any patient.

The CSF composition was normal, except for three patients with decreased CSF protein levels. The opening pressure on LP ranged from 230 to 450 mm of CSF; only one nonobese patient had an opening pressure less than 250 mm of CSF.

Treatment

All patients received standard headache therapy, including β-adrenergic antagonists, calcium channel antagonists, narcotic and nonnarcotic analgesia, enteral and parenteral ergotamine preparations, phenytoin, carbamazepine, fluoxetine, monoamine oxidase inhibitors, tricyclic antidepressants, lithium carbonate, cyproheptadine, *or* oxygen therapy at some point in their treatment (Table 2). Partial or temporary headache relief was attained; however, recurrence was the rule. All patients subsequently received trials of furosemide, acetazolamide sodium, or corticosteroids (dexamethasone/prednisone).

Three patients required surgical intervention when medical therapy failed to relieve headache. Two patients had a ventriculoperitoneal shunt; the other patient had a lumboperitoneal shunt.

All operations successfully eliminated incapacitating headache.

Follow-up

Of the seven patients who were treated with medical therapy and LP, one died, and six had intermittent severe headaches that required an LP and removal of CSF periodically to relieve symptoms (Table 2).

Patients were followed up for 2 months to 10 years. At subsequent examinations, papilledema had not developed in any of the patients.

COMMENT

Idiopathic intracranial hypertension without papilledema is rarely reported but may well be a clinically important syndrome. Our patients, except for the absence of papilledema, fit the following accepted criteria for IIH with papilledema[1-7] (Table 4):

1. Headache: Chronic tension-type headache with migrainous features is always present on awakening and associated with pulsatile tinnitus.
2. Patients: They are predominantly obese women aged 20 to 50 years.
3. History: Head trauma, meningitis, or subarachnoid hemorrhage are not uncommon.
4. Examinations: Physical and neurologic examination results are within normal limits, except for obesity and mild hypertension. No papilledema is present, but there may be a sixth nerve palsy.
5. LP: Lumbar puncture demonstrates increased CSF pressure with a normal composition (may show a decreased protein level).
6. Neuroradiology: The CT or MRI scans show no evidence of an intracranial mass or hydrocephalus (an empty sella may be present).

The patients had an elevated CSF pressure and essentially a normal CSF composition. Neuroradiologic studies showed an empty sella in two patients and small ventricles in one patient. Neuro-ophthalmologic examinations revealed pseudopapilledema with buried drusen in one patient. Along with IIH, chronic daily headache, female predominance, obesity, young age, normal laboratory study findings, or an empty sella were common findings in our patients (Tables 5 through 8).[17-23]

Pulsatile tinnitus was present in four of our patients. In a prospective study (conducted in 1987), Sismanis[24] found pulsatile tinnitus in each of 20 patients with classic pseudotumor cerebri. Wall and George,[25] in 1989, prospectively found that 60% of a group of patients with IIH had pulsatile tinnitus. The mechanism for this is thought to be vascular pulsation in CSF secondary to intracranial hypertension that is transmitted to the walls of the venous sinuses.[24]

There was a history of head trauma, meningitis, or subarachnoid hemorrhage in four of our patients. In 1980, Spence et al[14] reported that seven of nine patients with benign intracranial hypertension without papilledema had a history of head trauma. Traumatic subarachnoid hemorrhage or meningeal irritation with impairment of CSF flow might account for the elevated intracranial pressure in these patients.

All of our patients had a chronic daily headache present on awakening; this headache was frequently aggravated by analgesic or narcotic overuse (Table 3). The continuous chronic daily headache was often associated with more severe, intermittent, migrainous headaches. This might be a different variety of transformed or evolutative migraine, perhaps induced by weight gain. The quality of the pain varied from a dull ache to sharp and throbbing; however, most patients had a pulsating headache associated with nausea and vomiting (Table 9).

The mean duration of symptoms before diagnosis was 76.2 months (median, 36 months) compared with 3 to 5 months for patients with IIH.[18] The prolonged duration of symptoms may reflect a delay in performing an LP in patients with normal findings from neuroradiologic investigations and examinations. Our early patients had LPs done to rule out subarachnoid hemorrhage or meningitis following a change in the character or severity of their daily headache. Four patients had LPs performed after failure of maximal medical therapy. More recently, as a typical demographic and headache profile has emerged, we have been performing LPs earlier in the course of the illness (Table 10).

The headache of increased intracranial pressure is poorly defined, probably a reflection of the many causes of increased intracranial pressure, such as IIH, hydrocephalus, intracranial infections, and intracranial neoplasms. Wall[26] recently described the headache profile of 58 patients with IIH (Table 4). Severe, daily, throbbing, or pulsating pain associated with nausea, vomiting, hysical Examination, and Investigations*

*Plus sign indicates present; minus sign, no, none, or negative; ht/wt, height/weight; IBW, ideal body weight; BP, blood pressure; LP, lumbar puncture; OP, opening pressure; MRI, magnetic resonance imaging; CT, computed tomography; LABS, laboratory studies; HTN, hypertension; SZ, seizure; SYN, syncope; NA, not applicable; WNL, within normal limits; SVP, spontaneous venous pulsations; ND, not done; IBS, irritable bowel syndrome; CAD, coronary artery disease; SAH, subarachnoid hemorrhage; CSF, cerebrospinal fluid; MVP, mitral valve prolapse; Depr, depression; MVA, motor vehicle accident; BCPs, birth control pills; Thyr, hypothyroid; and PUD, peptic ulcer disease. All patients underwent ophtho/neuro-opthalmologic evaluations; no patient had papilledema.

†Medications associated with elevated intracranial pressure.

‡Percentage above IBW (% > IBW) with the use of the Metropolitan Age/Weight/Height tables.[16]

§Cerebrospinal fluid composition included cultures, VDRL, and determinations of protein and glucose values and cell counts. Only abnormal values are noted.

‖Laboratory studies included a complete blood cell count with a differential cell count, automated chemistry profile, and determinations of erythrocyte sedimentation rate, antinuclear antibody, rheumatoid factor, and triiodothyronine (routine urinalysis), thyroxine, thyrotopin (thyroid-stimulating hormone), and corticotropin values.

¶Right dense cataract.

and pulsatile tinnitus were common in his patients and in our series. Our patients' headache profile most closely approximates the combination of migraine and chronic tension-type headache as defined by International Headache Society classification.[27]

The frequency of IIH is about one case per 100 000 per year, or 19.3 in obese women aged 20 to 44 years.[17] Idiopathic intracranial hypertension without papilledema probably occurs in a subset of these patients and therefore would be expected to occur less frequently than 19.3/100 000 in women aged 20 to 44 years.[17] Ten to fifty percent of patients with brain tumors and increased intracranial pressure, proved by LP, may not have papilledema.[28] A prospective analysis of patients with typical demographic and clinical features of IIH without papilledema may further define the incidence of this entity.

Two of our patients had an empty sella as shown on a CT scan. Primary empty-sella syndrome is due to extension of the subarachnoid space through an incompetent diaphragma sellae, and increased intracranial pressure is thought to be a factor in its development. Papilledema is less frequent in patients with IIH with an empty sella. In the series of of Foley and Posner,[20] 50% of patients with increased intracranial pressure and an empty sella did not have papilledema. Thus, patients with chronic daily headache and an empty sella may have increased intracranial pressure even without papilledema.

The role of prolonged CSF pressure monitoring in diagnosis and management of IIH without papilledema is controversial. Twenty-four–hour CSF pressure monitoring was used in seven patients without papilledema to document abnormal pressure waves and increased intracranial pressure.[14] The greatest usefulness of this technique may be in monitoring selected patients whose CSF pressure by LP is normal or borderline elevated and who demonstrate headache relief after removal of CSF.

There is absolutely no evidence that IIH without papilledema is a threat to vision.[29-32] All but two of our patients had normal visual acuity and visual fields. One patient had pseudopapilledema with buried drusen, and the other patient had bilateral superior field defects. To our knowledge, these defects are nonspecific and not related to IIH. Ophthalmoscopic examinations done from 3 months to 2½ years after a first visit have not shown papilledema.

The presence of spontaneous retinal venous pulsations usually signifies normal intracranial pressure. Walsh et al[28] found that the mean pressure for obliterating spontaneous retinal venous pulsations was 200 mm of CSF. All but one of our patients had venous pulsations despite elevated intracranial pressure. The mechanism, which prohibits the development of papilledema in our patients, may also prevent the loss of venous pulsations despite elevated CSF pressure.

We believe that IIH should be considered even in the absence of papilledema. Patients with chronic daily headache, even if complicated by analgesic rebound, may benefit from LP early in the course of their illness. Increased intracranial pressure should be looked for, especially in women, 20 to 50 years,

Table 2.—Treatment and Follow-up*

†Follow-up until death.

with obesity, pulsatile tinnitus, history of head trauma or meningitis, headache on awakening, presence of an empty sella in imaging studies, or headache that is unrelieved by standard therapy.

Pathophysiology

The pathophysiology of IIH is unknown. Postulated mechanisms include (1) an increased rate of CSF formation, (2) an increased intracranial venous pressure, (3) a decreased rate of CSF absorption, and (4) an increase in brain interstitial fluid (edema). Recent studies have suggested that a decreased rate of absorption at the arachnoid villi and interstitial brain edema are the major contributors.[33-41]

Many mechanisms have been postulated for the absence of papilledema in patients with increased intracranial pressure as follows: (1) bilateral congenital optic nerve sheath defects; (2) bilateral acquired optic nerve sheath defects (subarachnoid hemorrhage, meningitis); (3) "chronic pseudotumor cerebri" with resolution of papilledema; and (4) intermittent elevation of intracranial pressure below the threshold to produce papilledema. Bilateral congenital optic nerve sheath anomalies may explain the absence of papilledema despite elevation of CSF pressure. The CT and MRI scans are normal; however, sensitivity and specificity of imaging in this setting is undetermined.[42-45] Autopsy or surgical documentation of optic nerve sheath defects may be helpful in future investigations.

Our three patients with head trauma and one patient with purulent bacterial meningitis may have had an acquired optic nerve sheath defect. In 1980, Spence et al[14] reported a series of nine patients with IIH without significant papilledema. Seven patients had had previous head trauma. Traumatic subarachnoid hemorrhage or meningeal inflammation with impairment of CSF absorption (and secondary arachnoiditis) may account for the absence of papilledema in the patients described by Spence et al[14] and us.

Chronic pseudotumor cerebri may explain IIH without papilledema.[27,29,46] Corbett et al,[29] in a follow-up study of 57 patients throughout a 5- to 41-year period, found persistent intracranial hypertension despite resolution of papilledema in seven of 10 patients, and half of

the patients had no characteristic fundus changes to suggest earlier papilledema. The chronic IIH postulate is supported by the chronicity of symptoms and the resemblance of our patients to those with classic IIH.

Intermittent elevation of intracranial pressure below the threshold needed to produce papilledema is another possibility. All but one of our patients had a persistent elevation of CSF pressure greater than 250 mm with serial LPs. The threshold pressure level needed to develop papilledema is unknown. We included a single case of a nonobese female with an opening pressure of 230 mm H$_2$O.

The mechanism of headache in increased intracranial pressure is unknown. Pseudotumor cerebri, high-pressure hydrocephalus, intracranial infections, hemorrhages, or neoplasms may produce headache and elevated intracranial pressure. However, as documented in patients with brain tumors, there can be headache without increased pressure. In a series of 72 patients, headache occurred as often in those without elevated intracranial pressure (19 of 23) as in those with increased pressure (46 of 49).[47] Traction on intracerebral pain-sensitive vessels, transient herniation of hippocampal gyri, and traction on cranial/cervical nerves with increased CSF pressure are postulated mechanisms of headache development. Alternately, changes in CSF pressure or flow may stimulate or inhibit central nervous system receptors (ie, adenosine receptors) that produce headache.

Treatment Modalities

The headache of patients with IIH and papilledema has frequently responded to standard headache treatment, including β-adrenergic blockers, calcium channel antagonists, antidepressant therapy, monoamine oxidase inhibitors, anticonvulsant therapy, analgesics, and ergotamine preparations. More aggressive surgical treatment of IIH has been directed toward preventing visual loss secondary to papilledema.

Table 5.—Demographics and Historical Findings*

Characteristic	Finding

Failure of standard headache therapy	10/10

*SAH indicates subarachnoid hemorrhage.

Table 6.—Physical Examination*

	Finding	No. of Patients
General examination	WNL	10/10
Blood pressure	WNL	10/10
Neurologic examination	WNL	10/10
Weight	Obese (24%-100% >IBW)	8/10

*WNL indicates within normal limits; IBW, ideal body weight.

Once the diagnosis of increased intracranial pressure is made, secondary causes should be sought out and eliminated. More than 50 diseases, conditions, toxins, or pharmaceuticals have been associated with IIH.[15] Obese patients should be encouraged to lose weight.

As in patients with classic IIH, patients with elevated intracranial pressure without papilledema should have a trial of standard headache therapy that, in general, diminishes duration or severity of headache but does not prevent its recurrence. Treatment of patients with IIH without papilledema should include (1) elimination of symptomatic causes, (2) weight loss if the patient is obese, (3) standard headache treatment, (4) carbonic anhydrase inhibitors and loop diuretics, (5) short course of high-dose corticosteroids, (6) serial LPs, (7) lumboperitoneal or ventriculoperitoneal shunts, and (8) possibly optic nerve sheath fenestration. These types of treatment are detailed further.

If aggressive headache therapy is unsuccessful, then diuretics or a potent carbonic anhydrase inhibitor (acetazolamide) should be given in a 4- to 6-week trial. These drugs have decreased the frequency and severity of elevated intracranial pressure headache.[1,31]

The use of high-dose steroids (prednisone or dexamethasone) is controversial, but may be effective.[1,15] Rebound headache is common when steroids are withdrawn. Their prolonged use produces many adverse side effects. If started, steroid therapy should be limited to a strict, short, 2- to 4-week trial.

Lumbar puncture typically relieves headache in IIH.[1,5,10] We removed enough CSF to decrease the intracranial pressure to 100 to 150 mm of CSF. Although all patients had immediate relief, headaches recurred in several days to several months. Cerebrospinal fluid is rapidly replaced. Prolonged symptomatic relief may reflect a persistent CSF leak. Alternately, transient reduction of CSF pressure may allow decompression of the arachnoid villi, allowing for prolonged enhanced CSF absorption. A repeated LP temporarily controls the headache of increased intracranial pressure. However, its long-term usefulness is controversial.

A patient with severe incapacitating headache that does not respond to medical therapy or repeated LPs may need surgical management. Subtemporal decompression, lumboperitoneal shunt, ventriculoperitoneal shunt, and optic nerve sheath fenestration have been used to treat patients with IIH and papilledema.[12,14,31,32,48-54] Subtemporal decompression is complicated by seizure and stroke, and it has largely been replaced with shunting procedures. In the report of IIH without papilledema by Spence et al,[14] six of nine of their pa-

tients were treated successfully with a lumboperitoneal shunt. Shunting procedures resolved elevated intracranial pressure headache in three of our patients; two patients had ventriculoperitoneal shunts, and the other patient had a lumboperitoneal shunt. Our three patients who required shunting procedures were severely incapacitated and unable to function before surgery. Two of these patients had postoperative LPs that showed normal CSF pressure at a time when they were free of headaches, and all three patients had significant improvement in their headaches.

Optic nerve sheath fenestration entails surgical incision of the dura mater that covers the optic nerve. The proposed mechanism in patients with IIH involves decompression of the optic nerve and continuous CSF drainage. In patients with papilledema and headache treated with optic nerve sheath fenestration, Corbett and coworkers[32] showed 65% efficacy in relieving medically uncontrolled headache. In 1988, Sergott and colleagues,[52] with the use of a modified optic nerve sheath decompression procedure, relieved headache in 13 of 17 patients with IIH. Optic nerve sheath fenestration has been performed on patients with unilateral papilledema but, to our knowledge, not on those patients with IIH without papilledema.

Follow-up

Patients with IIH without papilledema should undergo periodic neurologic follow-up. The neurologist should lower the intracranial pressure, control the headache, document changes in neurologic examination results, and encourage weight loss. The neurologist also should look for papilledema at every visit, since persistently elevated CSF pressure may predispose these patients to the development of papilledema and visual loss.

Neurologists, internists, and ophthalmologists who are faced with cases of severe, persistent headache with normal ophthalmoscopic examination results and normal findings from neuroimaging studies should rule out increased intracranial pressure.

The authors would like to thank James C. Corbett, MD, for his encouragement and helpful suggestions.

Tuberous Sclerosis Complex in Olmsted County, Minnesota, 1950-1989

Charles W. Shepherd, MB, MRCP; C. Mary Beard, RN, MPH; Manuel R. Gomez, MD;
Leonard T. Kurland, MD, DrPH; Jack P. Whisnant, MD

• The incidence of tuberous sclerosis complex in Olmsted County, Minnesota, was 0.28 per 100 000 person-years from 1950 through 1989, the point prevalence on December 31, 1989, was 6.9 per 100 000 persons, and the incidence at birth was 6.0 per 100 000 live births. The incidence was 0.13 per 100 000 person-years from 1950 through 1974 and 0.46 per 100 000 person-years from 1975 through 1989. The higher rate of diagnosis during the later period is believed to be due to the use of computed tomography. Of the 12 patients considered in this study, one patient presented with seizures and severe intellectual disability, six patients presented with seizures, three patients presented with multiple facial angiofibroma, and two patients were asymptomatic.

(*Arch Neurol.* 1991;48:400-401)

Tuberous sclerosis complex (TSC) is an autosomal dominant condition characterized by the presence of hamartomas and hamartias in one or more organs. Nearly any organ in the body can be affected. In the past, it was diagnosed only when a patient had seizures, severe mental disability, and multiple facial angiofibroma. We now know that these clinical features are only the tip of the iceberg and that there is a great variety of phenotypes[1] depending on the organ or organs affected. Since the introduction of computed tomography (CT)[2] in 1973 and magnetic resonance imaging in 1982, it has been easier to detect subependymal nodules and cortical tubers, allowing earlier diagnosis of the cerebral involvement by TSC. Likewise, renal CT or ultrasonography may detect hamartomas and cysts. Detection of these features has led to delineation of the different phenotypes.

In a study of the population of Rochester, Minn, Wiederholt et al[3] found the incidence rate of TSC to be 0.56 per 100 000 person-years and the prevalence rate to be 10.6 per 100 000 persons. From a study of all patients with TSC seen at the Mayo Clinic, Rochester, Minn, the original study has been updated and expanded to ascertain the birth and total incidence rates for the period 1950 through 1989 and the prevalence rate on December 31, 1989, in Olmsted County, Minnesota.

PATIENTS AND METHODS

All Olmsted County patients with a diagnosis of TSC were identified from the central records of the Mayo Clinic and the Olmsted Medical Group, which provide almost all of the medical care for local residents.[4] Patients were selected according to published criteria[5] (Table).

In addition to a review of all cases diagnosed as TSC during the 40-year period, a search was made for other cases of TSC by reviewing the records of patients registered since 1982 who had a dismissal diagnosis in one of the following categories: benign retinal tumor, fibroma, benign renal tumor, polycystic kidney disease, adenoma sebaceum, myoclonic seizures, infantile spasms, angiofibroma, cerebral hamartoma, and benign cerebral astrocytoma. Review of 555 records in this group yielded no additional cases.

For inclusion in the incidence study, the patients had to be bona fide residents of Olmsted County at the time of diagnosis. Any patient who had moved to Rochester to facilitate diagnosis and treatment was excluded from the incidence and prevalence studies.

Point prevalence was determined on December 31, 1989. The incidence rate, which covered the period 1950 through 1989, and the prevalence rate were calculated by using the decennial census data for the denominator. The 95% confidence intervals (CI) were based on the Poisson distribution.[6] The incidence rates are presented for the 40-year period and also for 1950 through 1974 and 1975 through 1989 to evaluate changes that may have occurred due to the introduction of CT in 1973 as a method of early diagnosis.

RESULTS

Twelve patients were considered in both the prevalence and the incidence studies. Two patients who resided in Olmsted County on the prevalence date were excluded from the incidence study, because their illness was diagnosed before they became residents of the County.

Ten patients (six male and four female) were first diagnosed as having TSC while living in Olmsted County during the study period. The mean patients' age at diagnosis was 14.7 years (range, 2 months to 53 years). The age-adjusted incidence rates per 100 000 person-years in the Rochester population with 95% CI were as follows: 1950 through 1974, 0.13 (CI, −0.02, 0.28), three cases; 1975 through 1989, 0.46 (CI, 0.11, 0.80), seven cases; and 1950 through 1989, 0.28 (CI, 0.01, 0.45), 10 cases.

The seven patients (four male and three female) with TSC, residing in Olmsted County (population of 101 974) on December 31, 1989, represent a prevalence rate of 6.9 per 100 000 persons (CI, 2.8, 14.4). Of the 66 478 children born to Rochester residents during 1950 through 1989, four were later found to have TSC, for a birth incidence of 6.0 per 100 000 live births.

Two patients who had participated in the previous study were excluded from this study. One of them, a child with TSC and severe mental disability, had

Criteria for Definitive Diagnosis of Tuberous Sclerosis*

Cortical tubers (on CT or MRI)
Subependymal glial nodules (on CT or MRI)
Retinal hamartomas
Facial angiofibromas
Ungual fibroma
Forehead or scalp fibrous plaque
Renal angiomyolipomas

*CT indicates computed tomography; MRI, magnetic resonance imaging.

been a resident in the Rochester State Hospital, but her condition was diagnosed before she entered the County and she was no longer an Olmsted County resident. The other had a diagnosis based only on a facial angiofibroma, and a new review of the skin biopsy sections failed to confirm this diagnosis.

In a family (Figure) with members who had TSC, four members (I-1, I-2, II-1, and III-2) were Olmsted County residents on the prevalence date. Two other members of this family known to be affected (II-2 and III-4) did not live in this county when diagnosed. One of the parents (generation I) must have TSC, because two of their children have it. The parents are both in good health, have no obvious stigmata of the condition, and have never had seizures. The CT scan of patient II-2 shows calcified subependymal nodules; this patient had seizures as a child and has numerous hypomelanotic skin macules. Her son, III-4, has many hypopigmented skin macules and had infantile spasms and partial seizures later; a magnetic resonance imaging of his head showed subcortical areas of increased signal in T2 sequences, which suggests the presence of tubers.

Of the nine other patients considered in either the prevalence or the incidence study, one boy (who died) had severe intellectual disability and seizures. Four patients with seizures have an average intellectual ability. In one of these patients, the diagnosis was based on the presence of multiple facial angiofibromas; in three other patients, who presented with seizures, the diagnosis was made by CT. Computed tomography was also used to make the diagnosis in the father of one of these patients, a resident of Olmsted County. The three remaining patients presented with facial angiofibroma.

Five of the seven patients who presented in the 1975 through 1989 period were diagnosed by CT.

COMMENT

The earliest studies to determine the frequency of TSC, done on patients in institutions for the mentally defective, suggested that the prevalence in the general population was about 1 per 100 000 persons.[7] Hunt and Lindenbaum[8] estimated the prevalence from source at 1:29 900 (3.3 per 100 000 persons) in the general population and at 1:15 400 (6.7 per 100 000 persons) among children under the age of 5 years. In an attempt at total ascertainment in the west of Scotland, Sampson et al[9] found a prevalence of 1:26 500 (3.8 per 100 000 persons) in the population and 1:12 000 (8.3 per 100 000 persons) for children under the age of 12 years. Point prevalence of TSC in our study, 6.9 per 100 000 persons, is very close to the results found in other populations. It is lower than the previous estimate for Rochester, 10.6 per 100 000 persons, but this difference is due to the exclusion of two of the patients included in the previous study.[3]

For the same reason, the overall incidence rate is lower in this study than in the previous one. Although based on a small number of cases and, therefore, very unstable, the incidence rate is higher in the more recent period. This may be due, in part, to the use of CT scan which allows an early diagnosis of TSC by detecting the subependymal nodules, and also reflects a better understanding of the nature of the disease, which led to the diagnosis in two asymptomatic cases. Magnetic resonance imaging helped to make the diagnosis in patient III-2, and it may be a useful way of detecting asymptomatic persons with TSC.

The birth incidence of 1:16 619 is lower, but not significantly, than is the prevalence rate in the general population of Olmsted County. It is possible that some affected persons who were born in Olmsted County had moved from the community prior to diagnosis of TSC. The diagnosis of TSC may be made in young children who present with infantile spasms[10] or other type of seizure, but the diagnosis may not be made until adulthood if the presenting symptom is not seizures but is the result of renal, pulmonary, or other pathologic conditions. It is clear that, in the present state of knowledge, birth incidence as determined in this study is not the best method of estimating the true incidence of TSC.

Of the 12 patients in our study, one patient had an intellectual disability and seven patients had seizures. In the larger study of all patients seen with TSC at Mayo Clinic and which, therefore, is influenced by referral bias, 48% had intellectual impairment and 78% had seizures.[11]

Because of small numbers, the Olmsted County study may not reflect accurately the number of patients that one would expect to find with an intellectual disability due to TSC, whereas the estimate of seizure prevalence in patients with TSC based on this study is more accurate. The small number of patients does not allow accurate estimation of the frequency of other pathologic conditions that are described in TSC. However, it does demonstrate that some cases of TSC are asymptomatic. Future population-based studies of TSC should include investigation of members of the families of those known to have TSC to provide a better estimate of disease frequency.

Standard and Controlled-Release Levodopa/Carbidopa in Patients With Fluctuating Parkinson's Disease on a Protein Redistribution Diet

A Preliminary Report

Patricia J. Karstaedt, MD; Jonathan H. Pincus, MD; Steven S. Coughlin, PhD

• Ten patients with Parkinson's disease (PD) with motor fluctuations that responded to a protein redistribution diet were studied. All 10 patients were receiving standard Sinemet (levodopa/carbidopa). Five randomly selected patients were changed from standard Sinemet to a controlled-release form of Sinemet. The other five patients continued to receive standard Sinemet. To maintain the same degree of control of PD in the five patients switched to the controlled-release form of Sinemet, the daily levodopa intake increased. While receiving optimal therapy (standard Sinemet or controlled-release Sinemet) and a protein redistribution diet, all 10 patients then underwent hourly videotaping and blood sampling (for plasma levodopa levels) during 2 consecutive days. Videotapes were blindly reviewed for PD disability, dyskinesia, and the time required to walk a measured distance. Comparing the two groups, standard Sinemet with controlled-release Sinemet, respectively, mean levodopa requirements were 505 and 1895 mg, plasma levodopa levels were 6.1 and 17.6 μmol/L, and abnormal involuntary movement scale scores were 14 and 26. Their mean PD disability scores did not differ statistically or clinically. Also no statistically significant differences were noted in either their mean walking times or their mean daily dose frequencies.

(*Arch Neurol.* 1991;48:402-405)

Motor fluctuations and unpredictable periods of levodopa unresponsiveness associated with dopamine replacement therapy can be difficult to control and are a major problem in the long-term management of advanced Parkinson's disease (PD).[1-6] Pharmacokinetic factors play a significant role in the deterioration of efficacy of levodopa.[3] To reach the central nervous system, plasma levodopa must cross the blood-brain barrier by a carrier-mediated mechanism. Large neutral amino acids compete with levodopa for this carrier. By simply eliminating daytime protein with a protein redistribution diet (PRD), sensitivity to levodopa (standard Sinemet) in many patients with fluctuating PD can be restored.[7-17]

Patients with severe PD can have depletion of more than 95% of brain dopamine stores.[18] In such cases, successful replacement therapy would, therefore, depend on the constant and continuous availability of levodopa. Several studies have reported that fluctuations can be eliminated by using continuous intravenous[3,19-22] and intraintestinal[23,24] levodopa infusions. The development of controlled-release dopaminergic preparations for oral administration has been encouraged by this successful, though usually impractical, use of continuous levodopa infusions.

One controlled-release form of Sinemet (Sinemet CR4, Merck & Co Inc, West Point, Pa) contains 50 mg of carbidopa and 200 mg of levodopa and is formulated in a slow-eroding matrix to allow for the gradual release of its contents. This formulation is designed to permit a more prolonged absorption of both ingredients resulting in the elimination of the sharp plasma levodopa peaks associated with standard Sinemet, while yielding higher end-of-dose plasma levels during long-term therapy.[25] Thus, peak antiparkinsonian effect is expected to occur later and last longer with the controlled-release preparation.[26] It may be most effectively used by patients requiring frequent dosing among whom are many with motor fluctuations.

Results from the use of this trial preparation are encouraging, but controlled-

released Sinemet has not been systematically compared with standard Sinemet in patients who are receiving a PRD. This preliminary report contrasts the effectiveness of these preparations in 10 patients receiving optimal therapy and a PRD. Optimal therapy was considered to be that dose and frequency of dose of drug (standard Sinemet or controlled-release Sinemet) that provided maximal relief of parkinsonian symptoms.

PATIENTS AND METHODS

Ten patients with moderate PD (Hoehn and Yahr stages 3 and 4), mean age of 64.7 years (range, 45 to 74 years), mean duration of disease of 10.7 years (range, 2 to 29 years), and mean duration of motor fluctuations of 3.4 years (range, 6 months to 9 years) that responded to and have been maintained on a PRD for a mean duration of 13.4 months (range, 5 to 24 months) were studied. All the patients were receiving optimal standard Sinemet therapy at the outset. To obtain optimal control of symptoms, four of the 10 patients were receiving adjuvant anti-PD therapy. These four patients did not differ from the other patients with repect to age at onset of PD, duration or severity of disease, or total daily dose and frequency of dose of levodopa. Their adjuvant therapy was unchanged during the course of the study.

Baseline outpatient clinical assessments (one per patient) were obtained on all patients. These included a PD disability score using the New York University (NYU) Disability Scale,[27] a dyskinesia score using the Abnormal Involuntary Movement Scale (AIMS),[28] and the time (in seconds) required to walk a measured distance, turn 180°, and return to the starting point.

Five patients, randomly selected, continued to receive standard Sinemet therapy (group 1) and the remaining five were changed to a regimen of controlled-release Sinemet therapy (group 2). No statistically significant differences were noted in age (65.8 and 63.6 years), duration of disease (14.6 and 10.6 years), NYU disability score (26.0 and 22.6), walking time (9 and 11 seconds), duration of fluctuations (4.1 and 2.7 years), or duration on the PRD (10.2 and 16.6 months) between the two groups (group 1 and group 2, respectively) at baseline. However, prior to being switched to controlled-release Sinemet, group 2 required a mean total standard Sinemet dose of 1165 mg, which was significantly greater ($P<.05$) than that required by group 1 (505 mg). Group 2 also required more daily standard Sinemet doses than group 1 (11.2 as compared with 6.0), although this difference was not statistically significant. In addition, three of the four patients maintained on a regimen of adjuvant therapy were randomized to group 1 and the fourth was randomized to group 2.

Once the controlled-release Sinemet dose and dosing frequency in the group 2 patients were optimized, a process that took 7 to 15 months (mean±SD, 11.4±3.6 months), a second outpatient clinical assessment was made of each of these five patients. The clinical scores, dose of levodopa, and frequency of levodopa administration obtained on these five group 2 patients when they were receiving optimal standard Sinemet therapy were compared with the corresponding values obtained when they were switched to optimal controlled-release Sinemet therapy using the paired *t* test (Table 1).

†Values are mean ± SE.

‡Represents eight data points per day, per patient, over a 2-day period.

The two groups were then further studied. All 10 patients (five receiving standard Sinemet and five receiving controlled-release Sinemet) underwent hourly videotaping of a standardized motor examination and blood sampling (for plasma levodopaa levels) from 9 AM to 4 PM on 2 consecutive days. Videotapes were separately reviewed and scored by a masked observer using the NYU scale, the AIMS, and the time (in seconds) to walk a measured distance. The number of "on" hours was also estimated from the videotapes. On time was regarded as that period that the patient was normal or mildly dyskinetic as opposed to "off" time in which the patient demonstrated signs of parkinsonism (ie, immobility, rigidity, and/or tremor). Scores obtained by patients in the two groups (standard Sinemet and controlled-release Sinemet) were compared using the Student's *t* test. Total daily levodopa dose and number of doses required by each group were also compared (Table 2).

One patient from group 2 then underwent hourly videotaping and blood sampling, from 10 AM to 4 PM as previously outlined, while receiving optimal controlled-release Sinemet therapy 1 day and then, after being restarted on a regimen of standard Sinemet, receiving optimal standard Sinemet therapy 3 days later. Scores obtained on each day were compared using the paired *t* test (Table 3).

RESULTS

To maintain the same degree of control of PD in the five patients changed from standard Sinemet to controlled-release Sinemet therapy, the mean daily levodopa intake increased significantly in four patients from 1356 to 2294 mg ($P<.05$) and decreased in the fifth patient from 400 to 300 mg while receiving standard Sinemet and controlled-release Sinemet therapy, respectively (Table 1). Overall, the mean daily dose increased from 1165 to 1895 mg, but this was not statistically significant (Table 1). The mean number of daily doses, comparing the five patients switched from standard Sinemet to controlled-release Sinemet therapy were 11.2 with standard Sinemet and 7.6 with controlled-release Sinemet (not statistically different).

Comparing the two groups, standard Sinemet with controlled-release Sinemet, respectively (Table 2), mean levodopa requirements were 505 and 1895 mg ($P<.05$). Plasma levodopa levels were 6.1 and 17.6 μmol/L ($P<.01$), AIMS scores were 14.0 and 26.0 ($P<.05$), and walking times were 17.2 seconds and 13.1 seconds (not significant). The PD disability scores were 22.6 and 22.2, respectively (not significant). Also no significant difference was noted in the daily dose frequency (6.0 and 7.6, respectively) or number of on hours per 8 hours of testing (5.6 and 6.6, respectively) between the two groups.

The results of the videotaping and blood sampling of the one patient from group 2 who was restarted on a regimen of standard Sinemet therapy are shown in the Figure. The total daily levodopa dose required by this patient dropped from 2800 (with controlled-release Sinemet) to 1600 mg (with standard Sinemet), total daily doses increased from eight (with controlled-release Sinemet) to 13 (with standard Sinemet), and mean plasma levodopa level dropped from 18.6 (with controlled-release Sinemet) to 8.4 μmol/L (with standard Sinemet). The patient's average PD disability score, dyskinesia score, and walking time were similar on the 2 days of testing (Table 3).

COMMENT

The much higher doses of levodopa necessitated by the controlled-release form of Sinemet were consequent to the formatting of the pill that contains 50 mg of carbidopa and 200 mg of levodopa. Higher dopa intake resulted in higher dopa blood levels and more dyskinesia, although PD disability scores and walking times were not significantly improved beyond the levels provided by standard Sinemet.

Raising blood dopa levels from moderate to high has been reported to cause dyskinesia without improving PD symptoms.[29,30] Controlled-release Sinemet did not permit a statistically significant reduction in the frequency of dosing, although some reduction in frequency did occur.

Table 3.—Comparison Between Controlled-Release Sinemet and Standard Sinemet in One Patient* Switched Back to Standard Sinemet From Controlled-Release Sinemet (Dosage Adjusted to Produce Optimal NYU Disability Score)†

Factor	Controlled-Release Sinemet	Standard Sinemet	Paired *t* Test

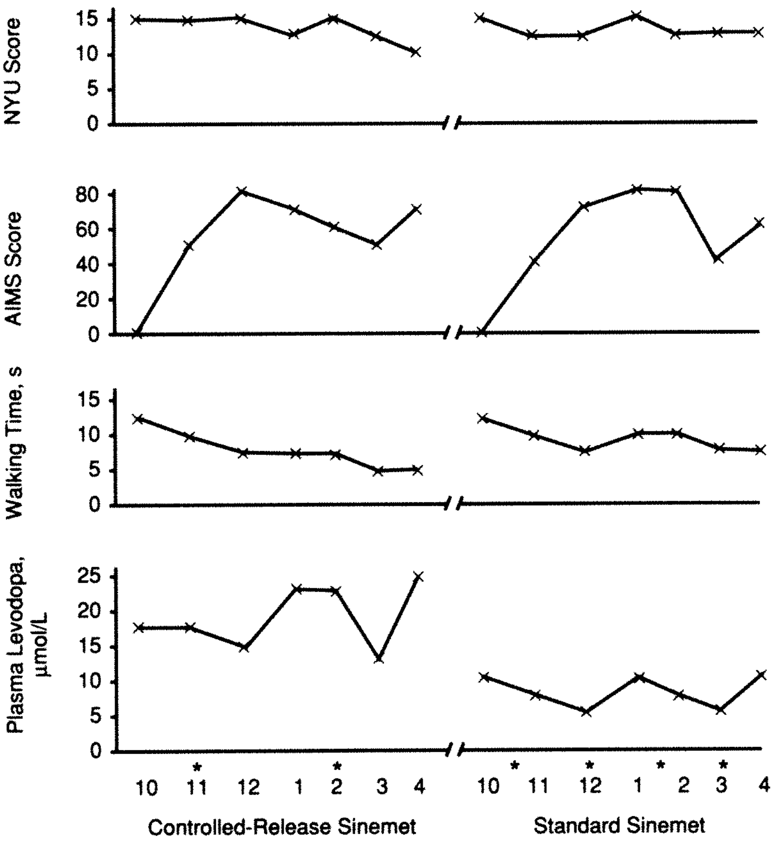
*The one patient from group 2 who was restarted on a regimen of standard Sinemet.

†NYU indicates New York University; AIMS, abnormal involuntary movement scale; and NS, not significant.

‡Represents seven data points over a 1-day period. Values are mean ± SE.



Analysis of response of patient receiving controlled-release Sinemet and then receiving standard Sinemet therapy. X axis indicates time of day (from 10 AM to 4 PM); asterisk, time of administration of Sinemet (standard or controlled release); NYU, New York University; and AIMS, abnormal involuntary movement scale.

The main reasons for using controlled-release Sinemet, as opposed to standard Sinemet, in patients with fluctuating PD would be to lower the dose frequency requirements and to increase on time while decreasing off time. In this regard, according to these preliminary data, controlled-release Sinemet was not particularly effective.

Although the patients were randomly allocated to treatment group, the small sample size resulted in a disparity in the baseline standard Sinemet requirements between group 1 and group 2. This may indicate that those patients in group 2 had more severe PD than their group 1 counterparts. However, no statistically significant differences were noted between the groups at baseline in age, duration of disease, NYU disability score, walking time, duration of motor fluctuations, or duration on the PRD. Furthermore, the additional data obtained on the one patient from group 2 who was restarted on a regimen of standard Sinemet therapy and then reassessed serves to support our preliminary conclusions.

Others have found some effectiveness of controlled-release Sinemet[31-36] in patients with fluctuating PD but did not simultaneously use the PRD. As the diet facilitates the central uptake of levodopa per se, its influence on both forms of Sinemet (standard and controlled release) would be the same, irrespective of their peripheral pharmacokinetic properties. However, the resultant improvement in the efficacy of standard Sinemet therapy is so dramatic[7-17] that, under conditions of daytime restriction of protein, treatment with controlled-release Sinemet does not seem to confer any further advantage. Further intrapatient trials of standard Sinemet and controlled-release Sinemet therapy, in conjunction with the PRD, involving larger numbers of patients will help to clarify the role of controlled-release Sinemet in patients who require the PRD.

This investigation was supported in part by Public Health Service grant NS 26605.

Angela Neal, RN, provided assistance with the videotaping of the patients.

Pneumocystis carinii Pneumonia in Patients With Primary Brain Tumors

John W. Henson, MD; Jai K. Jalaj, MD; Russell W. Walker, MD;
Diane E. Stover, MD; Anna O. S. Fels, MD

• **All histologically documented episodes of *Pneumocystis carinii* pneumonia in adult patients with primary brain tumors treated at Memorial Sloan-Kettering Cancer Center, New York, NY, since 1981, were retrospectively reviewed. *Pneumocystis carinii* pneumonia was histologically documented 11 times in 10 patients. During the same 8-year interval, approximately 587 adults were seen at the center for a brain tumor, 90% of whom received ongoing therapy. Therefore, in at least 1.7% (10/587) of our patients with brain tumors, *P carinii* pneumonia developed. The median duration of dexamethasone therapy at the onset of *P carinii* pneumonia symptoms was 2.75 months. Symptoms began during tapering of steroid therapy in eight episodes. Bronchoscopy was diagnostic in the eight cases in which it was performed. Four episodes (40%) were fatal. Trimethoprim-sulfamethoxazole prophylaxis may be indicated in some patients with brain tumors, especially during tapering of steroid therapy.**

(*Arch Neurol.* 1991;48:406-409)

Pneumocystis carinii is one of the most common opportunistic pathogens that causes pneumonitis in immunocompromised patients. There are a variety of predisposing immunodeficiency states, including hematologic malignant neoplasms.[1-5] In contrast, *P carinii* pneumonia (PCP) is rare in patients with solid tumors but may occur in these patients in the setting of corticosteroid therapy.[1,5-7] Patients with primary brain tumors often receive high doses of corticosteroids for prolonged periods, increasing the risk of opportunistic infections. To assess the magnitude of this problem in our patients with brain tumors, we reviewed all cases of PCP in patients with primary brain tumors treated at Memorial Sloan-Kettering Cancer Center (MSKCC), New York, NY. We determined the percentage of patients with brain tumors in whom PCP developed, the relationship of dexamethasone therapy to PCP, and the clinical features of PCP in this group of patients.

PATIENTS AND METHODS

The medical records of all adult patients treated at MSKCC since 1981 for a primary brain tumor and a histologically documented PCP diagnosis were reviewed. Cases were identified from the Memorial Hospital Data Analysis computerized database (containing diagnoses from clinic records of patients receiving their treatment at MSKCC, hospital discharge summaries, and autopsy reports) and from bronchoscopy records. To determine the size of the group at risk for PCP, we used the data analysis database to ascertain the total number of adults (aged ≥20 years) treated for a primary brain tumor from 1981 to 1989. Because pediatric patients with brain tumors at MSKCC are routinely treated with prophylactic trimethoprim-sulfamethoxazole during prolonged steroid therapy, we excluded all patients so treated from the group at risk by counting only patients who were at least 20 years old. To be certain that this database contained only patients who had ongoing therapy at MSKCC, 40 patients with a diagnosis of glioblastoma multiforme were selected from the group at risk for PCP and their records were reviewed for treatment and duration of follow-up.

In patients who underwent diagnostic bronchoscopy, bronchial washings and bronchoalveolar lavage were processed for bacterial, fungal, and mycobacterial staining and culture as previously described.[8] Cytologic examination was performed on bronchial brushings, washings, and lavage fluids using Papanicolaou and Gram-Weigert stains.[8] Gram-Weigert, Ziehl-Neelsen, and silver methenamine stains were performed on the transbronchial biopsy specimens in addition to the usual pathologic examination. All lung specimens were extensively examined and cultured, and their pathologic findings reviewed. *Pneumocystis carinii* pneumonia was diagnosed by the demonstration of cysts in bronchial fluid or lung tissue.

RESULTS

Patients With PCP

There were 11 histologically documented episodes of PCP in 10 patients with primary brain tumors between 1981 and 1989. The cases were distributed during this period as outlined in Table 1. Concurrently, 587 adult patients began treatment for a primary brain tumor at MSKCC. Approximately 90% of these 587 had follow-up adequate to identify episodes of PCP (see the following data). Therefore, during the last 8 years, PCP developed in at least 1.7% of our adult patients with brain tumors.

There were two patients with clinically suspected, but unconfirmed episodes, of PCP and two confirmed episodes in two patients with primary central nervous system lymphoma who were excluded from analysis. Of the remaining 10, six patients were men and four were women; their median age was 45 years; and all were white. The tumors were

Reprint requests to Department of Neurology, Memorial Sloan-Kettering Cancer Center, 1275 York Ave, New York, NY 10021 (Dr Walker).

glioblastoma multiforme (five), anaplastic astrocytoma (three), brain-stem glioma (one), and medulloblastoma (episodes at the ages of 26 and 29 years occurred in this patient). The brain tumor was in the posterior fossa in six of the patients (medulloblastoma, brain-stem glioma, midbrain and thalamic glioblastoma, multifocal anaplastic astrocytoma, cerebellar anaplastic astrocytoma, and cervicomedullary junction anaplastic astrocytoma).

The interval from the time of tumor diagnosis to the time of diagnosis of PCP ranged from 3 weeks to 9 years, with a median of 3 months. Nine tumors were newly diagnosed and two were recurrent, one at 3 years and one at 8.5 years from the original tumor diagnosis. The patient with two episodes of PCP suffered the second episode during a recurrence 3 years following the original diagnosis.
